The first of the theories that link temperament and motivation focuses on trait adjectives (Eysenck and Eysenck, 1987; McCrae and Costa, 2003). The Big Five (McCrae and Costa, 2003) and the Big Three (Eysenck and Eysenck, 1987) are the most common models representing this line of research. The big five factors are neuroticism (i.e., tendency to be distressed, worried, nervous, and insecure and hold low opinion of oneself), extraversion (i.e., tendency to be outgoing, sociable, and enthusiastic but also somewhat impulsive and heedless), openness to experience (i.e., tendency to be imaginative, curious, analytical, and having insight and a broad perspective on life), conscientiousness (i.e., tendency to be hardworking, self-disciplined, responsible, reliable, and well-organized), and agreeableness (i.e., tendency to be warm, cooperative, helpful, patient, empathic, and sincere) (McCrae and Costa, 1987), whereas the big three is composed of neuroticism, extraversion, and psychoticism (i.e., tendency to be highly impulsive, aloof, nonconforming, aggressive, and lacking responsibility vs cooperative, empathic, tender-minded, and conventional) (Eysenck and Eysenck, 1987). Psychoticism has associations mainly with Agreeableness and Conscientiousness from the Big Five, but also with Extraversion and Neuroticism via its strong impulsivity component (McAdams, 2009). Conscientiousness and Openness have been found to explain 17% of the variance in intrinsic motivation (Komarraju et al., 2009), which is seen as the most significant motivation type particularly in educational and occupational settings. Of the variance in extrinsic motivation, Conscientiousness and Extraversion have been shown to explain 13%, whereas of the variance in amotivation, Conscientiousness and Agreeableness have been found to explain 11% (Komarraju et al., 2009).

The second theory that may link temperament and motivation is founded on Psychobiological Model of Temperament and Character developed by Cloninger et al. (1993), which has been mentioned before. The theory conceptualizes the variation between individuals by facilitative and inhibitory motivational systems that are basic to the structure of temperament and personality. Cloninger's temperament traits are suggested to be linked to brain activity with perceptual memory systems associated with different activities of neurotransmitters (Novelty Seeking with low basal dopaminergic activity, Harm avoidance with high serotonergic activity, Reward dependence with low basal noradrenergic activity, and Persistence with no special neural correlates, as told before) (Cloninger et al., 1993). Therefore, they are also indicated reflecting preconceptual or subconscious biases in the emergence of motivated behavior and in learning (Cloninger et al., 1993). The functional interaction of these dimensions (i.e., multidimensional temperament profiles) manifests in individual differences in information processing and associative learning (i.e., operant conditioning of habits and automatic and affective reactions to perceptual stimuli) in response to novelty, punishment, and reward (Cloninger et al., 1993). What comes to learning and working circumstances, getting into novel situations and receiving rewards and punishments are common experiences and therefore, temperament is highly relevant in these situations. Persistence, for example, has been associated with students' intrinsic academic motivation after adjustments for age and gender (Tanaka et al., 2009).

The third theory to link temperament and motivation is the theory developed by Gray (1970). This theory focuses on two basic motivational systems that shape and modify an individual's behavior and affect; (1) the behavioral activation system that is suggested to facilitate behavior and to create positive affect and (2) the behavioral inhibition system that is suggested to inhibit behavior and to create negative affect. Studies have shown that Behavioral activation system, Positive emotionality, and Extraversion load on Approach Temperament factor, whereas Behavioral inhibition system, Neuroticism, and Negative emotionality load on Avoidance Temperament factor (Elliot, 2006; Elliot and Thrash, 2002). Both approach and avoidance temperaments have been shown to be systematically linked to achievement goals (Elliot and Thrash, 2002), which in turn serve a directional function in approach-avoidance motivation and predict motivated behavior (Elliot, 2006). The hierarchical approach-avoidance motivation is proposed to come from two significant origins – temperaments and motives – which form a foundation for the achievement goals (Elliot, 2006).

The association of temperament with avoidance-approach motivation has also been examined in terms of personal goals related to avoidance/approach (Bjørnebekk and Diseth, 2010; Elliot and Thrash, 2002; Heimpel et al., 2006), achievement goals based on the hierarchical model of achievement motivation (Chen and Zhang, 2011), and in the context of the expectancy-value model (Tempelaar et al., 2011). Temperamental Activity, Flexibility, and Task orientation, as well as Neuroticism, Extroversion, and Conscientiousness, have been shown to predict mastery-approach, mastery-avoidance, performance-approach, and performance-avoidance goals (Chen and Zhang, 2011). Openness and Agreeableness, in turn, have been shown to predict the mastery-oriented and performance-oriented achievement goals, respectively (Chen and Zhang, 2011).

As the fourth theory linking temperament and motivation Derryberry and Rothbart have introduced a dynamic and interactive model of temperament, motivation, and attention. In this theory, temperament consists of three factors: surgency extraversion (i.e., dimensions of impulsivity, activity, sociability, approach, and high-intensity pleasure); negative affect (i.e., dimensions of discomfort, fear, anger/frustration, and sadness); and effortful control (i.e., dimensions of low-intensity pleasure, smiling/laughter, inhibitory control, perceptual sensitivity, and attentional focusing), the latest one being the most significant temperament dimension for attentional functions (Derryberry and Rothbart, 1997; Rothbart et al., 2007). Differences in a motivational affect, in turn, are associated with the direction of attention toward or away from a stimulus (Derryberry and Reed, 1994; Derryberry and Rothbart, 1997). The interaction between temperament, motivation, and attention manifests as individual differences in reactivity (i.e., the excitability of motor activity, affect, and endocrine and autonomic responses) and self-regulation (i.e., processes that either enhance or inhibit reactivity) (Derryberry and Rothbart, 1997).

The foregoing four theories share an agreement that individual differences in both temperament and motivation evolve partially from the reactivity of underlying neural systems, which influence individual differences in attentional, motivational, and self-regulatory functions (Chang and Burns, 2005; Deci and Ryan, 2000; Derryberry and Reed, 1994). As a result of these underlying influences, individuals with different temperaments will be exposed to and become motivated by different types of information and environmental stimulations, leading to different content within their "motivational and developmental representations" (Derryberry and Rothbart, 1997, p. 633).

Although temperament and motivation are relatively independent of cognitive ability (e.g., Guerin et al., 2003; Hintsanen et al., 2012; Oliver et al., 2007), temperament-based differences in emotional reactivity, energy level, motivation, and attention are significantly associated with the educational outcomes, in particular with the ability to persist and settle down to the task at hand, and show what one has learned (Rothbart and Jones, 1998). Mastery motivation is seen as an inborn and intrinsic disposition that refers to the positive versus negative affect/approach versus inhibition system, which is further strongly linked with an individual's tendency to experience reward and punishment in achievement and control-related situations (Barrett and Morgan, 1995; Rothbart and Jones, 1998).

Practically, mastery motivation is composed of task persistence, preference for challenge or novelty, and a tendency to control one's environment, but a tendency to show effortful control and a tendency to experience fear or frustration are also possible contributors (Rothbart and Jones, 1998). Rothbart and Jones have emphasized that teachers should receive thorough temperament-conscious teacher training in order to understand the differences of students' behavioral characteristics in emotional reactivity and attentional self-regulation, which are significant factors in educational and occupational settings (Rothbart and Jones, 1998).

Interaction between temperament and motivation on attention may be mediated via individual differences in reactions to stressful situations (Chang and Burns, 2005). Among children with performance-oriented motivation, the levels of effortful control have been suggested to regulate children's stress tolerance, and to further affect their attentional skills. However, among children with mastery-oriented motivation, the level of effortful control did not play a strong role in attentional abilities until the assignment was really stressful (Chang and Burns, 2005).

Abstract

Temperament is defined as biologically rooted, early appearing dispositions that shape long-term patterns of socioemotional development. Much of the research has focused on broad dimensions of emotional reactivity, including positive and negative emotionality, and regulation, marked by effortful control. The article outlines five main research traditions that have approached temperament as both a continuous and a categorical construct. For each model, descriptions are provided for the dimensions/category proposed and their defining features, the underlying constitutional bases, and perspectives on temperamental continuity and discontinuity. Next, theoretical and measurement issues are discussed. Finally, we demonstrate how temperament may predict developmental psychopathology through temperament-by-temperament and temperament-by-environment moderations of early risk.

Introduction

Temperaments reflect biologically based individual differences in how children interact with, and adapt to, their environments across development, leading to marked interpersonal variations in both normative behavior and psychopathological profiles. The landmark round table discussion on temperament at the 1985 meeting of the Society for Research in Child Development (Goldsmith et al., 1987) presented four core models of temperament. The models each focused on early emerging, constitutionally based, multidimensional constructs, emphasizing the stability of temperament as a motivator of behavior, while recognizing that the expression of temperament may change across time (Rothbart and Derryberry, 1981) and contexts (Goldsmith and Campos, 1982). No consensus was reached regarding the conceptual 'boundaries' of temperament. For example, Thomas and Chess (1977) confined temperament to observable behavioral styles. Goldsmith and Campos (1982) defined temperament during infancy as the presence of primary emotions. Finally, Rothbart and Derryberry (1981) included cognitive processes as core components of temperament.

Despite these discrepancies, each model pursues a dimensional approach to temperament, quantifying temperamental variations along a continuous spectrum. In contract, Kagan (Kagan et al., 1984) takes a typological approach to temperament. He and colleagues identified a temperament category, behavioral inhibition (BI), characterized by hypervigilant and withdrawal behavior in response to unfamiliar people and situations in toddlerhood and childhood. Together, the five models have provided multidisciplinary (and complementary) assessment tools and theoretical frameworks for studying temperament and its development. These include parent- and self-report questionnaires, laboratory observations of behavior, psychophysiological measures, and behavioral genetic approaches.

Contemporary temperament research focuses on studying how intrinsic (neural and cognitive processes) and extrinsic (environmental) processes interact to moderate the continuity of temperament and influence the link between early temperament and subsequent socioemotional adjustment. This article will discuss (1) the five major approaches to temperament (Table 1); (2) current theoretical and methodological issues in research on temperament development; and (3) the mechanisms by which documented relations between temperament traits and maladjustment are moderated by other temperament traits (temperament × temperament moderation) and environmental factors (temperament × environment moderation). We take the perspective that early temperament does not determine developmental outcomes. Rather, temperament traits interact with internal and external factors to influence individuals' risks and resilience to events and contexts that shape developmental trajectories.

Theoretical Approaches to Temperament

The Thomas and Chess Approach

The New York Longitudinal Study stands as a landmark in temperament research. Thomas and Chess (1977) focused on behavioral styles characterized across nine dimensions: activity level, regularity, approach withdrawal, adaptability, threshold of responsiveness, intensity of reaction, quality of mood, attention span/persistence, and distractibility. Children are categorized into 'difficult,' 'easy,' and 'slow to warm' types based on their scores on each dimension. Moreover, Chess and Thomas introduced the concept of 'goodness of fit,' suggesting that optimal developmental outcomes are more likely to emerge when the child's temperament is closely matched to the demands, expectations, and opportunities of the environment (a good fit). Conversely, a mismatch between temperament and environmental characteristics is more likely to result in maladaptive outcomes (Thomas and Chess, 1977).

The Buss and Plomin Approach

Buss and Plomin (1975) proposed a behavior-genetics-oriented model, proposing that temperament traits have an early onset and are inherited, evolutionary adaptive, present in nonhuman animals, relatively stable during development and predictive of later behaviors. They identified three core dimensions: emotionality (E), activity (A), and sociability (S), each captured by the EAS Temperament Survey (Buss and Plomin, 1984). The approach utilized twin studies to

Table 1 Summaries of the five theoretical approaches to temperament

	Defining features	*Dimension(s)/Type(s)*	*Underlying biological mechanisms*	*Major instrument(s)*	*Key reading(s)*
Thomas and Chess	● Represent stylistic components of behavior	Dimensions: ● Activity level ● Regularity ● Approach withdrawal ● Adaptability ● Threshold of responsiveness ● Intensity of reaction ● Quality of mood ● Attention span/persistence ● Distractibility Types: ● Difficult ● Easy ● Slow to warm up	Not discussed	1–3 years old: The Toddler Temperament Scale (TTS; Fullard et al., 1984); 3–7 years old: The Behavioral Style Questionnaire (BSQ, McDevitt and Carey, 1978); 8–12 years old: The Middle Childhood Temperament Questionnaire (MCTQ, Hegvik et al., 1982).	Thomas and Chess (1977)
Buss and Plomin	● Inherited traits ● Evolutionary adaptive ● Present in our phylogenetically related species ● Early emerging and relatively stable in childhood ● Preserved in adulthood	Dimensions: ● Emotionality ● Activity ● Sociability ● Impulsivity (dropped)	Temperament dimensions have genetic bases.	EAS Temperament Survey (EAS, Buss and Plomin, 1984)	Buss and Plomin (1975) Buss and Plomin, (1984)
Goldsmith	● An emotional phenomenon; ● Related to individual differences; ● Behavioral tendencies rather than actual observable emotional behavior; ● Does not contain cognitive and perceptual components; ● Has cross-situational generality and short-term stability rather than being transitory.	Assessed in Lab-TAB: ● Activity level ● Positive affect ● Fear ● Anger ● Sadness ● Shyness ● Approach ● Persistence ● Inhibitory control	Temperament dimensions are genetically influenced	Toddler Behavior Assessment Questionnaire (TBAQ, Goldsmith, 1996); Laboratory Temperament Assessment Battery (Lab-TAB, Goldsmith and Rothbart, 1993)	Goldsmith and Campos (1982, 1986);
Rothbart	● Biologically based ● Contains reactive and regulatory aspects	Dimensions: ● Negative affect ● Surgency ● Effortful control	The attention network: Encompasses the anterior cingulate cortex and the lateral prefrontal regions	3–12 months: The Infant Behavior Questionnaire (IBQ, Rothbart, 1981); 18–36 months: The Early Childhood Behavior Questionnaire (ECBQ, Putnam et al., 2006); 3–7 years: The Children's Behavior Questionnaire (CBQ, Rothbart et al., 2001); 7–10 years: The Temperament in Middle Children Questionnaire (TMCQ, Simonds and Rothbart, 2004); 9–15 years: The Early Adolescent Temperament Questionnaire (EATQ, Capaldi and Rothbart, 1992)	Rothbart and Derryberry (1981) Rothbart and Bates (2007)
Kagan	● Biologically based and early emerging ● Defined a specific temperament category characterizes children who show elevated physiological reactivity, hypervigilance and withdrawal upon encountering novel stimuli (behavioral inhibition)	Type: Behavioral inhibition	Hyperresponsive amygdala	Not developed	Kagan (1994); Kagan and Fox (2007)

quantify genetic contributions to individual variance in temperament traits (Buss and Plomin, 1984). Monozygotic (MZ) twin pairs showed significantly larger correlations in all three EAS traits versus dizygotic (DZ) twins. Given that MZ twins have twofold more genetic similarity than DZ twins, the greater phenotypic similarity in MZ twins indicates genetic influences on trait variance (Saudino, 2009).

The Goldsmith Approach

Goldsmith and Campos (1982) defined temperament as individual differences in the propensity to express and experience primary emotions (e.g., joy, anger, and fear). Individual differences in temperament are reflected in variations in intensive and temporal parameters of behavior, including facial expressions, gestures, vocal and motor behaviors. The definition is restricted to infant temperament, in order to obtain a relatively 'pure' conceptualization of temperament expressions unmediated by socialization influences and cognitive processes. However, recent variants of the model include emotion regulation as a defining feature, as emotion expression and regulation might not be separable, even in infancy (Campos et al., 2004).

Goldsmith and colleagues developed the Toddler Behavior Assessment Questionnaire (Goldsmith, 1996), and the age-adapted Laboratory Temperament Assessment Battery (Lab-TAB; Goldsmith and Rothbart, 1993; **Table 1**). The Lab-TAB provides a series of standardized behavioral tasks and coding schemes that assess temperament dimensions in emotion-eliciting episodes in the laboratory or at home. It stresses that the context of behavior needs to be considered in measuring temperament, since the eliciting situations affect the expression of temperament dimensions (Goldsmith and Gagne, 2012).

Building on their initial conceptualization, Goldsmith and colleagues focused on the psychobiological processes underlying emotion reactivity and regulation. For example, Buss et al. (2004) combined both Lab-TAB and physiological measurements and found that heightened fearfulness in a mildly threatening situation was associated with heightened baseline sympathetic reactivity a week later. This implies a possible association between fearful temperament and reduced physiological regulation.

The Rothbart Approach

The Rothbart model (Rothbart and Derryberry, 1981) provides a more inclusive conceptualization, defining temperament as biologically rooted individual differences in reactivity and self-regulation in emotional, activational, and attentional processes. Reactivity refers to levels of biological arousal triggered by changes in internal and external stimulations, captured as dimensions of negative affect and surgency. Self-regulation refers to the processes that modulate reactivity (Rothbart and Derryberry, 1981) and is reflected in the temperament dimension, effortful control (EC). Taking a dimensional approach, each of the three higher-order dimensions is comprised of lower-order temperament traits (Rothbart and Bates, 2007).

Questionnaires from this approach assume heterotypic continuity in temperament development (Caspi, 1998). That is, age-appropriate questions or eliciting tasks take different forms of expression but are thought to evoke the same underlying bases throughout development (Fox and Henderson, 1999). As presented in Rothbart and colleagues' age-specific questionnaires, the broad dimensions remain stable, but the specific traits indexing each dimension changes across age groups. For example, EC during early infancy is measured as a form of involuntary attention orienting. As external controls become internalized, indices of EC come to also encompass attention shifting and focusing (Rueda, 2012).

The Rothbart model is unique in prominently placing self-regulation as a core component of temperament. EC has been studied with multiple-levels of analyses, including the aforementioned parent- and self-report questionnaires, as well as computerized cognitive tasks and laboratory observation tasks. Findings from computerized tasks demonstrate that EC capacities, including error detection and conflict resolution, first emerge at the end of first year of life and continue to improve during late childhood and into adolescence (Rothbart et al., 2007; Rueda, 2012). Neuroimaging research adopting these marker tasks suggests that the development of EC is subserved by the executive attention network, a neural system centered on the prefrontal cortex (Posner et al., 2014).

As EC develops during toddlerhood, it exerts 'brakes' on unregulated negative emotionality and motor activities (Rothbart and Derryberry, 2002), and enhances children's abilities to adapt to environmental demands. Longitudinal data indicate that higher EC predicts less negative emotional arousal. Conversely, elevated negative emotionality predicts lower EC efficiency (Eisenberg et al., 2010). At the neural level, efficiency in regulating reactivity is subserved by the coupling between regions associated with regulation (e.g., the prefrontal regions) and reactivity (e.g., the amygdala and the striatum; Dennis, 2010). The continued dynamic and reciprocal interactions between temperamental reactivity and regulation contribute to the observed instability of temperament expression over time (Rothbart and Bates, 2007).

The Kagan Approach

Distinct from dimensional approaches to temperament, Kagan and colleagues defined BI as a temperamental *category* characterized by discrete biological dispositions: high psychophysiological reactivity coupled with hypervigilance and behavioral withdrawal upon encountering novel people, objects, and events (Kagan et al., 1984). Kagan's approach emphasizes the use of behavioral observations and biological measures instead of parent-report questionnaires (Kagan, 2003). Based on laboratory observations, 4-month-old infants who displayed elevated motor reactivity and distress toward novel visual and auditory stimuli were categorized as 'high reactive' (Kagan and Snidman, 1991) or 'high negative' (Fox et al., 2001). BI in young children (14–48 months) is examined by coding their behavior toward unfamiliar people and objects. Assessment in older children (4 years to school age) focuses on their interactions with unfamiliar peers. Hence, Kagan's approach also focuses on heterotypic continuity of temperament development over time (Fox et al., 2001). Kagan and colleagues found that although not all high-reactive infants become behaviorally inhibited in childhood, the percentage of high-reactive infants

who are later categorized with BI was greater than those who were identified as uninhibited (Kagan, 2003). Fox et al. (2001) showed that at 14 months, infants who were classified as 'high negative' displayed higher levels of BI than those who were identified as 'low reactive' or 'high positive.'

Kagan proposed that the neurobiological foundation of BI is rooted in a highly excitable amygdala, which predisposes children to become hypervigilant toward unfamiliar stimuli (Kagan, 2012), and contributes to the moderate stability of BI (Fox et al., 2005). Adults who were identified as 'high reactive' at 4 months showed greater amygdala responses when presented with neutral unfamiliar faces compared to those who had been 'low reactive' (Schwartz et al., 2003, 2011). Moreover, Pérez-Edgar et al. (2007) found that, compared to non-inhibited adolescents, adolescents with sustained BI in childhood showed elevated amygdala response while rating how afraid they were of emotional and neutral faces. The amygdala has extensive connections to cortical areas that contribute to behavioral avoidance and deficient safety learning observed in behaviorally inhibited individuals (Schwartz et al., 2011).

Stable BI across childhood is a risk factor for anxiety disorders, especially social anxiety disorder (SAD, Pérez-Edgar and Fox, 2005a). BI and anxiety disorders have a range of overlapping behavioral, cognitive, and neurological features. Retrospective evidence suggests that adolescents and adults with anxiety symptoms also reported higher levels of social withdrawal in childhood (Degnan et al., 2010). Additionally, Clauss and Blackford's (2012) meta-analysis showed that the risk for SAD increases sevenfold for behaviorally inhibited children. However, only 43% of behaviorally inhibited children developed SAD. The central tenet of the Kagan's approach argues that early BI does not necessarily predict stability of temperament and later anxiety disorders. Rather, it constrains possible socioemotional development outcomes (Kagan and Fox, 2007).

Current Methodologies and Issues in Temperament Research

Contemporary temperament research has shifted its focus from debating the defining features and structure of temperament (Goldsmith et al., 1987) to studying developmental trajectories from early temperament to subsequent socioemotional adjustment outcomes. Summarizing the shared viewpoints and new perspectives on temperament since the round table discussion, Shiner et al. (2012) define temperament as early appearing traits in the domains of motor activity, emotion, attention, and self-regulation. They stress that temperament is the product of the continuous influences of genetic, biological, and environmental processes throughout development.

First, traits may have different developmental courses, and those that come online later during infancy and childhood (e.g., regulatory traits) may affect the expression of existing traits' (e.g., temperamental reactivity; Rothbart and Derryberry, 1981). Second, assessments of temperament, including the questionnaires developed under the Rothbart approach (Rueda, 2012) and laboratory observation tasks (Lab-TAB, Goldsmith and Rothbart, 1993; BI tasks, Fox et al., 2001), reflect a priori conceptualization of heterotypic continuity in temperament development (Caspi, 1998). Third, although temperament traits are biologically based, behavioral genetic research has found only moderate genetic influences. Rather, both genetic and environmental factors, especially nonshared environmental influences, contribute to the stability and change of temperament over time (Saudino and Wang, 2012).

There is an on-going debate regarding whether specific temperament traits are best captured as variations along a continuum or qualitative differences across distinct categories. Support for the typological approach has come from sophisticated modeling analyses (Loken, 2004), which replicated Kagan and Snidman (1991)'s categorization of high-reactive infants. Moreover, BI profile is associated with distinct profiles of neural reactivity evident in limbic (Pérez-Edgar et al., 2007; Schwartz et al., 2003, 2011) and striatal (Helfinstein et al., 2012) responses to salient stimuli. However, this association was not found when BI was treated as a continuous variable (Pérez-Edgar et al., 2013). Yet, longitudinal studies using discrete BI profiles (e.g., Chronis-Tuscano et al., 2009) and those adopting continuous measures of BI (e.g., Muris et al., 2001) have provided converging results, both suggesting that BI predicts greater risks for SADs. Hence, both categorical and dimensional conceptualizations could potentially provide useful frameworks to study the link between early temperament and later psychopathology (Clauss and Blackford, 2012).

Cultural Influences on Temperament

The influences of cultural values on temperament development are nonnegligible. Culture creates a bioecological environment (Bronfenbrenner and Morris, 2006) that encompasses children's physical and social environment. Parents' cultural belief system influences how they perceive, evaluate, and respond to their children's temperament, which, in turn, shape children's temperament development and adjustment (Super and Harkness, 2002). In studying the impacts of immigration and involvement in the host culture (i.e., acculturation) on parental perception of infant temperament, Gartstein et al. (2009) found that among Russian families who immigrated to the United States, greater adherence to Russian culture was correlated with higher ratings of child positive emotionality. In contrast, for immigrants to Israel, greater parental involvement in Russian culture was linked to lower child positive emotionality. Moreover, Russian parents with greater acculturation to Israeli society rated their children higher on orienting and focusing of attention.

Cultural norms may shift parental perception of what traits are adaptive, which, in turn, affect parental practice, how the child's temperament is manifested, and the parent's perception of their child's temperament (Gartstein et al., 2009). For example, BI is associated with greater maternal warmth and acceptance in Chinese children, whereas Canadian children with BI experience more maternal rejection (Chen et al., 1998). Furthermore, early BI predicted subsequent social and academic competence among Chinese children (Chen et al., 1999, 2009a). Greater social acceptance of BI in China, in contrast to findings from the West, may facilitate adaptive socioemotional development. However, Chen et al. (2009b)

also found increased maladjustment in inhibited Chinese children from urban areas, likely due to rapid Westernization. Taken together, the cross-cultural studies support the presence of cultural difference in temperamental reactivity and regulation and associated developmental outcomes.

Issues Relating to Measurement Approaches

Temperament assessments target naturally occurring behaviors reported by caregivers, behaviors elicited by laboratory controlled tasks, and neurophysiological correlates of these behaviors (Goldsmith and Gagne, 2012; Rothbart and Bates, 2007). Across approaches, temperament research stresses the adoption of a multimethod perspective (Kagan and Fox, 2007). Multiple measurement approaches complement each other to overcome limitations of a specific method, and together they provide insights into unique aspects of temperament. Caregiver reports have been criticized for being biased, unreliable, invalid, and limited in revealing the underlying mechanisms of overt traits (Kagan and Fox, 2007). However, Rothbart and Bates (2007) argue that parent reports provide unique information on children's general behavioral tendencies across different situations.

Laboratory observations allow for relatively objective assessments of microlevel information on latency, duration, and frequency of facial, vocal, and gestural responses to specific elicitors that are inaccessible to verbal reports and neurological measures. However, behavioral coding may be subject to experimenters' biases, observations may lack ecological validity, and laboratory triggers may elicit emotional states rather than measuring temperament traits (Goldsmith and Gagne, 2012). Despite these limitations, laboratory observations, particularly the Lab-TAB battery (Goldsmith and Rothbart, 1993), allow for flexibility in behavioral coding and data reduction compared to questionnaire assessments (Goldsmith and Gagne, 2012). This advantage is reflected in research on dysregulated fear (DF). Buss (2011) adopted a multilevel modeling approach to capture changes in fear behaviors across episodes low, moderate, and high in contextual threat. The analyses identified a DF profile in two-year-olds, characterized by high levels of fear in low threat and benign contexts (e.g., playing with puppets and a clown). This is different from the analytic method used to identify BI, where behavioral parameters are aggregated across episodes containing different levels of threat. Buss et al. (2013) found that children characterized with DF were four times more likely to show social anxiety symptoms at the transition to kindergarten than other fearful children. Children characterized with DF might be a more homogeneous group within BI that is associated with a developmental trajectory to social anxiety.

Behavioral genetics, as a theoretical and empirical approach, has made prominent contributions to evaluating the relative contributions of genetic, shared, and nonshared environmental effects on the continuity and instability of temperament (Saudino, 2009). It also provides a tool to examine the cross-method and cross-situation validity of temperament measures. For example, Saudino and Zapfe (2008) found different genetic influences for activity levels assessed at home versus the laboratory. These findings suggest that different instruments and measurement contexts may tap into distinct etiology of observed behaviors. Therefore, caution must be taken when making generalizations across data gathered from different measurement tools under different contexts.

Temperament and Developmental Psychopathology

A temperament trait may act as a risk or resilience factor that predisposes individuals to psychopathology or protects them from disorders, in part by influencing the child's experiences with the external environment and their exposure to additional risk or protective factors (Lengua and Wachs, 2012). The developmental psychopathology perspective stresses that temperament is an etiological factor that should be studied in interactive systems, in order to reflect the complex, transactional nature of developmental processes, in which adjustment outcomes are the result of successive adaptations that build upon one another (Sroufe, 2009). This includes both temperament-by-temperament interactions and temperament-by-environment interactions in predicting outcome (Zentner and Bates, 2008).

Temperament × Temperament Moderation

The framework of temperament-by-temperament moderation is rooted in the Rothbart approach, which highlights the interplay between reactive and self-regulatory components of temperament in shaping developmental trajectories. For example, components of EC moderate the link between BI (as negative reactivity) and anxiety. BI is associated with increased attention toward potentially threatening stimuli (Pérez-Edgar and Fox, 2005b), which is likely to elicit a cascade effect on subsequent information processing, leading individuals to encode and interpret relatively neutral social information as threatening, which in turn produces maladaptive behaviors such as social withdrawal. These processes influence each other through a feedback loop, contributing to the formation of a response repertoire that perpetuates and strengthens anxious behaviors over time. Indeed, longitudinal studies indicate that childhood BI strongly predicts subsequent social withdrawal only in adolescents and children displaying attention biases to threat (Pérez-Edgar et al., 2010a,b, 2011), suggesting that attention bias acts as a 'tether' to predispose children with BI to a developmental trajectory marked by elevated anxiety symptoms (Pérez-Edgar et al., 2014). In contrast, executive attention control, as an EC function, facilitates voluntary attention shifts from threat and a subsequent focus on more positive cues, which may, in turn, allow for better self-regulation of emotion and behavior (Lonigan and Vasey, 2009), decreasing the risk for anxiety in high-BI children (White et al., 2011).

Inhibitory control and response monitoring are two additional EC components that may impact the expression of temperamental reactivity. While better inhibitory control and response monitoring is associated with reduced externalizing and internalizing symptoms for most children (Eisenberg et al., 2010), high levels of these EC abilities in behaviorally

inhibited children increase their risks for the developing anxiety problems (Degnan and Fox, 2007; Lahat et al., 2014; McDermott et al., 2009; White et al., 2011). Presumably, when involuntary control functions, such as heightened reactivity, are combined with high voluntary control systems (i.e., EC functions), they may increase behavioral rigidity and inability to adjust to environmental demands (Derryberry and Rothbart, 1997).

Temperament × Environment Moderation

The conceptualization of temperament–environment interactions are in line with the mechanisms associated with gene-by-environment interplay. First, temperament traits influence how children perceive and react to positive and negative reinforcements from the environment (Shiner and Caspi, 2012). For example, threat-related attention biases may predispose behaviorally inhibited children to perceive negative aspects of the environment as more salient (Pérez-Edgar et al., 2014; Todd et al., 2012). This facilitates the learning of negative associations linked to their behavior (Shiner and Caspi, 2012), which may, in turn, lead to the emergence and maintenance of anxiety (Pérez-Edgar et al., 2014).

The second mechanism is environmental elicitation, suggesting that individual differences in children's temperament elicit different parenting behaviors. Social withdrawal in behaviorally inhibited children may evoke parental overcontrol (Rubin et al., 2009), which may limit children's opportunities to attain social competency. Indeed, parental overcontrol moderates the link between early BI and subsequent anxiety symptoms (Lewis-Morrarty et al., 2012).

In environmental selection, children actively select specific niches in their environments that are compatible with their temperament, which may, in turn, influence their exposure to risks (Shiner and Caspi, 2012). Rubin et al. (2006) found that behaviorally inhibited children are more likely to have best friends who are also more socially withdrawn and victimized compared to the best friends of noninhibited children. Such dyads may perpetuate social withdrawal, leading to continued rejection from larger peer groups and vice versa (Degnan et al., 2010).

Finally, environmental construal refers to the processes by which temperament shapes individuals' environmental exposure through influencing social cognition (Shiner and Caspi, 2012). From repeated experience of social rejections, children may develop an attributional schema characterized by self-blame for negative experiences (Rubin et al., 2008), as well as avoidant coping strategies (Wichmann et al., 2004). These attributional and coping styles may form a self-reinforcing cycle that leads to continued withdrawal and internalizing symptoms (Rubin et al., 2009).

A number of theoretical models have been proposed to explain how certain temperament traits make individuals more susceptible to aversive or supportive social environments (Lengua and Wachs, 2012; Reiss et al., 2013). The goodness-of-fit model originating from Thomas and Chess' (1977) approach emphasizes that children whose temperament matches the characteristics of their environment will have better adjustment outcomes than those who have a poorer fit. The traditional diathesis–stress model suggests that given the same amount of environmental adversity, temperamentally at-risk children will develop more adjustment problems compared to children without these risks. Negative emotionality, including anger/frustration and fearful temperament, is considered to be a direct risk factor for both externalizing and internalizing symptoms (Lengua, 2002) and may be shaped by parenting. For example, permissive parenting styles predict more internalizing symptoms in behaviorally inhibited children versus uninhibited children (Williams et al., 2009), while a rejecting parenting style is linked to increased externalizing symptoms in high-frustration but not low-frustration children (Lengua, 2008).

Extending from the diathesis–stress model, the differential susceptibility model (Belsky and Pluess, 2009) argues that temperamentally at-risk individuals may not only be more affected by negative experiences, but could also benefit the most from supportive environments, relatively to children with less temperamentally based sensitivity to the environment. Negative emotionality is likely to be a susceptibility marker (Belsky and Pluess, 2009). Compared to children with an 'easy' temperament, children with high negative emotionality display more behavioral problems during the transition to schools if they experienced low-quality day care, but they show fewer problems if they received high-quality day care (Pluess and Belsky, 2009). Moreover, temperamental irritability is associated with lower attachment security. At the same time, the beneficial effects of an intervention on attachment are significantly greater for highly irritable versus moderately irritable infants (Cassidy et al., 2011). The model underscores the importance of studying phenotypic and genetic markers of sensitivity to environmental influences, as well as both risk and resilient contextual factors for socioemotional development.

General Conclusions

Theoretical approaches to temperament have not reached a full consensus regarding the inclusive criteria and structure of temperament. Working definitions of temperament incorporate the domains of affectivity, self-regulatory processes, and motor activity in their conceptualization of the construct (Shiner et al., 2012). There is solid agreement that temperament is a multilevel construct, which is observable via behavioral and neurobiological measurements, and is continually influenced by genetic, biological, cognitive, and environmental factors. Developmental psychopathology and behavioral genetic perspectives provide theoretical and methodological frameworks to study temperament as a biologically based risk or resilience factor that influences individuals' trajectory to certain socioemotional adjustment outcomes through complex interactive processes involving individuals' own cognition, affect, and their external developmental contexts. Different temperament traits impose inherent vulnerability (e.g., high negative emotionality) or resilience (high EC) mechanisms that influence outcomes by moderating individuals' exposure to negative or enriching environments, constraining what environmental

characteristics are beneficial or harmful to specific temperament traits. Temperament traits also affect individuals' level of susceptibility to both aversive and favorable environmental influences. These dynamic interactive processes support the fundamental notion that temperament does not determine developmental outcomes. Rather, it sets the complex foundation on which multiple actors come together to shape developmental outcomes (Kagan, 2003).

Temporal Distinctiveness Models of Memory

Gordon DA Brown, University of Warwick, Coventry, UK

Abstract

Temporal distinctiveness models of memory are described and the history of their development is reviewed. Evidence that memory is temporally organized is discussed, and it is shown how temporal distinctiveness models account for a range of data from short-term and long-term memory tasks without assuming the existence of a separate short-term memory system.

Introduction

This article is about temporal distinctiveness models of memory. But what does it mean to say that something is distinctive? In everyday language, we say that something is distinctive to the extent that it is different from other things. A wine may have a distinctive aroma; a person may have a distinctive laugh. When thinking about memory, a similar concept of distinctiveness can be applied. Memories that are distinctive are memories that are different from, and hence unlikely to get confused with, other memories. Distinctiveness is seen as the inverse of similarity. Distinctiveness models of memory must specify exactly how to measure distinctiveness and also need to explain how the distinctiveness of memories makes them easy or difficult to recall.

We can introduce memory distinctiveness using a spatial analogy. It is now common to think of memory as being like a large space in which long-term memories – such as the meanings of words in a language – and also short-term memories occupy their own locations. Memory retrieval then requires finding the place in memory where the target is to be found. At an intuitive level, the process can be seen as analogous to picking out an object from an array of other objects on a table. Imagine a fairground stall in which an array of prizes to be won is scattered around on a large table some distance away from you. The prizes differ in value, and your task is to throw a counter onto the table. You receive whichever prize your counter has landed closest to. Of course, you want to receive one of the more valuable prizes, so you aim to throw your counter so that it settles closer to your target than to anything else. The more isolated your target item is (the more empty space it has around it), the easier this task will be. If there are many low-value prizes close to your high-value target, then your throw will have to be very accurate in order to win the prize. In this case, the location of the prize on the table is less distinctive – it occupies a similar location to many others, and hence you may by accident get one of the other prizes. Retrieving items from memory can be thought of as analogous. The counter that you throw onto the table is like a retrieval cue that you put into memory space. If the item that you are trying to retrieve from memory occupies a fairly isolated region of memory (i.e., there are relatively few very similar items that occupy nearby locations in memory, and hence interfering with your search), it will be easier to retrieve your target item.

Later we will show how recent models of memory quantify these notions of similarity, distance, and distinctiveness. First, however, we need to explain the idea of *temporal* distinctiveness. We explain temporal distinctiveness in terms of an analogy, introduced by Crowder (1976), which captures the intuition that underlies a number of distinctiveness approaches to memory, reviewed below, which were developed in the early 1970s. Crowder asked us to imagine a line of evenly spaced telephone poles that are being passed by a moving train. To an observer on the train, relatively nearby telephone poles (poles that have just been passed) are easy to discriminate from one another – they are distinctive. However, as the train moves on and the telephone poles recede into the distance, they become increasingly difficult to discriminate from one another – they become less distinctive. According to Crowder's analogy, we can think of memories receding into the past as time moves on just as the telephone poles recede into the spatial distance as the train moves on. Thus the central idea of temporal distinctiveness models of memory is that items become less discriminable from one another, and hence less distinctive and harder to retrieve, as they fade into the past in just the same way as telephone poles become less discriminable as they recede into the spatial distance. Next, we will discuss how this general idea led to a series of increasingly sophisticated temporal distinctiveness models of memory.

History

We first consider an approach to memory distinctiveness represented by what we term global distinctiveness models, then show how global distinctiveness models have been supplemented by local distinctiveness models. We then note a variety of more general temporal context models, which have developed in parallel and some of which can be seen as implementing the principles of temporal distinctiveness.

Early Global Distinctiveness Models

More than half a century ago, Murdock (1960) put forward an influential distinctiveness model of memory and identification. The underlying idea was that the distinctiveness of an item can be defined as the sum of its distances from other items in a context (the context could be something like a list of items to be retrieved or a set of objects differing in weight). For example, consider a five-item list of words to be recalled using their serial

positions within the list. The items to be remembered are (A B C D E), and their serial positions in the list are therefore [1 2 3 4 5]. Consider the second item, B. This position of B (i.e., 2) is one different from the position of A, one different from the position of C, two different from the position of D, and three different from the position of E. Therefore the summed difference of the position of B from the position of the other four items is $1 + 1 + 2 + 3 = 7$. If we calculate the summed difference for every item in this way, we end up with [10 7 6 7 10]. It is often then convenient to divide these numbers by the total, which gives us [.25 .175 .15 .175 .25] – a measure of the relative distinctiveness of each item. (For the purposes of this illustration we ignore possible transformations of items' values along a dimension, which will often be important.) These numbers make a plausible serial position curve – items near the end of the series are more distinctive than the mid-series items. This type of distinctiveness model – i.e., with distinctiveness calculated as the summed difference between an item and all other items – was extended by Neath (1993) to describe items' distinctiveness along a temporal dimension. Neath applied the model to primacy and recency effects in memory and their interactions with retention interval. We refer to this type of model as a *global distinctiveness* model, and note that it is quite different from the type of model that we outlined in the introduction. Going back to the fairground example, the difficulty of making your counter land close to your target prize is determined by the distance between the target and its nearby neighbors on the table. The distance between the target prize and a faraway prize, on the other side of the table, will not make the target any easier to win. We refer to models as *local distinctiveness* models (Neath et al., 2006) when it is mainly the similarities of nearby items, rather than the similarities of distant items as in the global distinctiveness model, that matter most. Considerable evidence, from both perceptual and identification tasks and memory research, supports the idea of local rather than global distinctiveness, and from this point on when we talk about 'distinctiveness' we will be referring solely to local distinctiveness.

Local Distinctiveness Models

The 1970s saw the development of a number of local distinctiveness models of memory, although they were not always labeled as such at the time. Most of the early models are often called *ratio-rule models*. Bjork and Whitten (1974) were interested in the explanation of recency effects in memory, which disappear after a filled retention interval but can reappear if the time that separates to-be-remembered items is increased (so-called long-term recency effects). They suggested that memory performance would depend on two amounts of time – the time separating items in a list to be remembered, and the time elapsed since those items were presented. This approach can be illustrated by the telephone pole analogy. Imagine that the telephone poles are separated by 5 m. Now consider the difficulty of discriminating two telephone poles that are 20 and 25 m away (analogous to two memory traces that were laid down 20 and 25 s in the past). The ratio of these two distances (or times) is $20/25 = 0.8$. If the difficulty in discriminating the telephone poles – or memories – depends on the ratio of their distances from the observer (of telephone poles) or recaller (of memories), then the distant items will be more confusable than the items that are just 5 and 10 (meters or seconds) away because in the latter case the relevant ratio is only $5/10 = 0.5$. Increasing the temporal gap separating items in a to-be-remembered list will reduce confusability even if temporal distance is constant.

A number of ratio-like models of memory emerged (e.g., Baddeley, 1976; Glenberg and Swanson, 1986, and several others). These early ratio-rule accounts can be seen as types of local temporal distinctiveness model. In stating that discriminability of a pair of items depends on the amount of time separating them, ratio models claim that the discriminability of an item is reduced just by the nearest of its closest temporal neighbors. Indeed it can be argued that ratio rule models are actually *too* local, and that the distinctiveness of an item in memory will likely be reduced not just by its single closest neighbor, but also (albeit perhaps to a lesser extent) by other nearby neighbors. The fact that the ratio-rule models we have described are so local means that – although they are good at accounting for recency effects (as with the telephone pole analogy)– they cannot without modification account for primacy effects – i.e., the tendency for several items near the start of a list to be better remembered than those in the middle portions of the list. A simple ratio rule model predicts that, if memories are evenly spaced in time, they become ever less distinctive as they recede into the past; there is no mechanism for primacy effects to emerge.

There are two ways in which primacy effects can be explained while preserving the basic idea of the ratio rule. One possibility is that rehearsal of early list items effectively increases their recency, by carrying the items forward through the list, with the result that a simple ratio-rule model can account for primacy effects, as well as recency effects, when rehearsal-induced recency is taken into account (Tan and Ward, 2000). Such an account offers the appealing prospect of being able to account for both primacy and recency effects, as well as differences between memory tasks, with a single simple model (Ward et al., 2010).

Another way of accounting for primacy effects within a temporal distinctiveness framework is given by a recent extension of temporal ratio models, called SIMPLE (Scale-Invariant Memory, Perception, and Learning: Brown et al., 2007b). SIMPLE states, as do some temporal ratio models, that the confusability of any two items in memory will depend on the ratio of the items' recall intervals (i.e., their temporal distances from the point of recall). However, this applies to every pairwise combination of items – although the confusability of an item with its nearest temporal neighbors will be most important, more distant temporal neighbors will also exert an influence, although their influence will be smaller. For example, consider four memory traces that were laid down 20, 19, 18, and 17 s in the past. The oldest item (that occurred 20 s ago) will be 19/20 confusable with the next oldest item, but also 18/20 confusable with the third item in the list and 17/20 confusable with the fourth item in the list. The distinctiveness of an item in memory is assumed to be inversely proportional to the sum of the item's confusabilities with all other items in a list. Brown et al. show that such an account, where all items in a target's temporal neighborhood can cause interference, can

account for primacy effects for the first few items in a list even without the assumption of rehearsal. This is because the items at the end of the list only have neighbors (from which they must be discriminated) on one side of them. Another difference between SIMPLE and earlier ratio-rule models is that SIMPLE contains a free parameter, which raises the temporal distance ratios to a power–this parameter effectively governs the rate at which confusability increases with temporal distance ratio. Brown et al. (2007a) and Neath and Brown (2006) show that this extended version of a ratio-like temporal distinctiveness model can account for a range of effects from both serial and free recall memory tasks.

Temporal Context Models

The temporal distinctiveness models outlined so far offer rather abstract descriptions of memory retrieval as a temporal discrimination process. The more general idea that constraining memory search using temporal/contextual cues might be important in memory retrieval also has a long history (e.g., Glenberg et al., 1983). More recently, the temporal/contextual model of working memory (Shipstead and Engle, 2013; Unsworth and Engle, 2006) suggests that low working memory capacity is associated with problems in locating sufficiently precise temporally defined regions of long-term memory.

What sorts of mechanisms, perhaps closer to a neural network level of description, might underlie such accounts? Several models have assumed that a temporal/contextual signal of some kind becomes associated with events at the time they are learned. To the extent that the relevant temporal/contextual signal can be used as a retrieval cue, items that were associated with it can be recalled. The idea that contextual elements, often ones assumed to change gradually over time, can become associated with events is not new (see e.g., Bower, 1972; Hintzman et al., 1973; Mensink and Raaijmakers, 1988). More recent models instantiate the idea of temporal context in various ways. For example, the OSCAR model (Brown et al., 2000) assumes the neural availability of an array of oscillators, similar to those used in independently developed models of timing (Church and Broadbent, 1990) which create a time-varying context signal to which items become associated. Reinstatement of the context signal allows it to wind forward, reconstructing the state at presentation and leading to serial recall (see also Houghton, 1996). A recent model by Farrell (2012) assumes that clusters of items are represented as episodes by being linked together through their associations to a common temporal context, and the model accounts for a wide range of findings from serial and free recall memory tasks.

Although space prevents a comprehensive review of temporal context models, not all such models are appropriately categorized as temporal distinctiveness models. For example, the influential temporal context model and its successors (e.g., Howard and Kahana, 2002; Polyn et al., 2009; Sederberg et al., 2008) has, as a key component, a temporal context that provides part of the learning context for a given item. The learning context is also given partly by preexperimental associations, and whenever an item is retrieved there is an associated recall of the learning contexts associated with the recalled item. The retrieved learning context will tend to cue recall of items that were studied nearby in time. This type of model may predict that temporally isolated items will be less well recalled than nearby items (i.e., the opposite prediction to the one normally made by a temporal distinctiveness account) because a retrieved cue will act as a less good probe for items that were studied at a greater temporal distance from the last recalled item (Polyn et al., 2014).

To summarize: Temporal distinctiveness models of memory have two core features. First, they assume that memory is chronologically organized – that is to say, memories of events that occurred nearby in time are located in nearby locations in memory. Second, they assume that memory traces that are more temporarily isolated will be more distinctive and easier to retrieve. Some, but not all, temporal distinctiveness and temporal context models also emphasize the continuity of memory over widely varying timescales – that is, they assume that the same principles of temporal distinctiveness underpin both short-term and long-term memory tasks, without assuming a distinction between underlying short-term and long-term stores. We now explore each of these assumptions in more detail.

The Temporal Organization of Memory

What does it mean to say that memory is temporally organized? Human episodic memory has long been viewed as a system for storing and retrieving temporally dated episodes (Tulving, 1972). A key claim of current temporal distinctiveness models of memory is the specific idea that human episodic memory is organized in such a way that the temporal relationship between the time an event occurred and the time of remembering is represented in the memory system. We should note that this is not the same as the claim that memories are somehow labeled with the calendar time they occur; there are considerable problems with such an account. The claim is that the temporal distances from the present, rather than some calendrical representation of the temporal location at which it occurred, is what is relevant.

Moving beyond the claim that memory is chronologically organized, an obvious question is *why* it might be so. Some researchers have argued that a 'rational analysis' of memory can be undertaken, such that the time course of forgetting reflects the organization of an optimally designed memory system in which the memories that are most likely to need to be retrieved are the ones that are easiest to retrieve. Anderson and Schooler (1991) demonstrated that items that have been encountered more recently are more likely to need to be retrieved, and that the decay of 'need probability' (the probability that an item will need to be recalled) occurs over time in a manner paralleled by the form of the forgetting curve. Thus time may be a basic organizing dimension in a memory system that adaptively reflects the statistical structure of the events in the world that it must remember.

Furthermore, as Gallistel (1990) has noted, it may be that the temporal (as well as the spatial) coordinates associated with an event form a crucial component of memory records in order to enable the unity of remembered experiences to be maintained. In addition, provided time can be represented as nonrepeating, the provision of temporal coordinates provides

a unique address for every item. Stored temporal information is used by many animals for both foraging and navigation (Clayton and Dickinson, 1988; Gallistel, 1990).

Thus there are several reasons why an implicit representation of temporal distance in the past may be an important component of memories. It should be borne in mind that claims of temporal distinctiveness models are, however, stronger than simply the claim that time is an important underlying dimension of memory; models may assume that time is important without necessarily predicting effects of temporal distinctiveness.

Serial Position Curves and Forgetting

What sorts of evidence are relevant to evaluating temporal distinctiveness models of memory, and how do the models account for key memory phenomena? We first give a brief explanation of how temporal distinctiveness models account for serial position curves and forgetting, and then examine sources of evidence that test specific predictions.

The intuitive explanation for recency effects in temporal distinctiveness models of memory is the one illustrated by the telephone pole analogy described earlier – items become less discriminable from one another as they recede into the temporal distance. We illustrate this, as well as how temporal distinctiveness can explain primacy effects, with a worked example based on the SIMPLE model.

Figure 1 shows a list of four to-be-remembered items (the filled squares), with the passage of time moving from left to right. Each item has written above it its temporal distance from the time of recall (i.e., its distance from the present). Consider the second item in the list. This has a temporal distance of 6 s, meaning that it occurred 6 s before the time of recall. The distinctiveness of the item in memory will depend on its confusability with other items along the temporal dimension – the more confusable it is, the lower will be its discriminability. These confusabilities will depend on the temporal distance ratios, so that the confusability of the item with the first list item will be 6/8, its confusability with the third list item will be 4/6, and its confusability with the final list item will be 2/6. We also have to consider the similarity of the item to itself, which is always 1.0. The sum of these confusabilities is then 2.75, and the discriminability of the item in memory will be inversely proportional to this summed confusability, i.e., it will be 0.36.

We can calculate the discriminabilities of the other three items in the list in exactly the same way, and they turn out to be 0.40, 0.38, and 0.48 for the first, third, and fourth items, respectively.

Figure 1 Illustration of the temporal distances from the point of retrieval of four items in a to-be-remembered list.

This worked example illustrates three key points. First, as shown earlier, there is a general trend for items further in the past to be less distinctive than more recent items – as in the telephone analogy and in earlier 'ratio-rule' models within a local temporal distinctiveness framework. Second, unlike in the earlier ratio-rule models, the first item on the list is more distinctive than the second item on the list (0.4 vs 0.36) – a primacy effect. The effect is only visible for the very first item in our example, because the list is very short. If we did the same calculation for a longer list, however, the primacy effect would extend over many more items. Third, we can see how forgetting and the reduction of recency effects occur. Consider, for example, the second and the fourth items (which have distinctiveness values of 0.36 and 0.48, respectively). Suppose we now increase the retention interval from 2 s to 32 s. This will lead to every item becoming more confusable with its neighbors. For example, the similarity of the first and second items, originally 0.75 (the ratio of their temporal distances; 6/8) will now be $36/38 = 0.95$. Because all the temporal distances are larger, all the ratios are increased and the distinctiveness of all items is reduced. In fact the distinctiveness values for all items after the delay, taking into account the confusability of each item with the other three, are 0.27, 0.26, 0.26, and 0.27. It is evident that, because of the ratio properties of the temporal distance confusability measure, the most recent item loses much or all of its relative advantage in distinctiveness. This can again be understood in terms of the telephone pole analogy – if one walks away from the end of the line of telephone poles, the poles that one was previously standing next to lose their relative advantage in discriminability. Although this account is only a simplified version of a complete model (which would also incorporate mechanisms to allow for items to be either recalled or not recalled as a function of their distinctiveness), it captures the essence of one temporal ratio model of memory.

In the remaining sections, we illustrate the types of evidence appropriate to evaluation of temporal distinctiveness models of memory, and consider how the models relate to wider issues of memory organization.

Evidence for Temporal Distinctiveness

Various types of experiments have tested the claims that memory is temporally organized and that temporal distinctiveness influences recall, and we review these in turn.

Memory as Temporal Discrimination

Distinctiveness models assume that memory retrieval is akin to temporal discrimination. One approach is to test this assumption directly by using temporal discrimination tasks and asking whether the discriminability of particular durations of time can predict the recallability of memory items that have corresponding distances in the past. Consider a task in which participants are required to identify tones in terms of their temporal duration (e.g., telling a 0.5 s tone apart from a 0.75 s tone; telling apart a 1.0 s tone from a 1.5 s tone). In a series of experiments examining both the discriminability of different temporal durations and memory for letters and words, Brown et al. (2009) found that the relative memorability of list

items mirrored the relative discriminability of temporal durations (the tones) that corresponded to the temporal distances of the to-be-remembered items. These results appear consistent with the idea that memory retrieval involves temporal discrimination.

Related work examines whether time, rather than the number of interfering events, influences memory judgments. Hintzman (2004) presented lists of words that varied in presentation rate, with some items being repeated. On encountering a repeated item, participants were asked to judge the number of items that had intervened since the last presentation of the item. Hintzman found that the amount of intervening time, rather than the number of intervening words, determined the judgment. If it is assumed that recency judgments are based on the difference between the learning contexts associated with the two occurrences of the relevant item, this result seems consistent with temporal accounts in which the contextual signal changes with the passage of time.

Time and forgetting

What causes forgetting? In particular, is it the passage of time since an item entered memory, or the number of interfering events (such as other items in a to-be-remembered list) that have occurred since the item entered memory, that determines forgetting? The debate about whether time or interference causes forgetting considerably predates temporal distinctiveness models but is relevant to their evaluation.

A temporal distinctiveness model of the type described above argues that forgetting can occur due to the passage of time alone even though interference alone is responsible for retrieval failure and no trace decay occurs (cf. the analogy of evenly spaced telephone poles receding into the distance and becoming less discriminable from one another). This no-decay assumption contrasts with the claims of many influential models of short-term and working memory, according to which, traces decay as time passes (e.g., Barrouillet et al., 2004; Page and Norris, 1998). Space does not permit a review of the large current literature on the causes of short-term forgetting. Although recently some authors have argued against forgetting due to time-based decay in short-term and working memory (Berman et al., 2009; Lewandowsky et al., 2004, 2009), the issue remains controversial both theoretically and empirically (Altmann and Schunn, 2012; Barrouillet and Camos, 2012; Campoy, 2012; Ricker and Cowan, 2010).

The key point here is that, evidence that forgetting occurs due to the passage of time alone does not in itself provide evidence for or against temporal distinctiveness models. Instead, deciding between trace decay models and temporal distinctiveness models requires examination of the *relative* temporal spacing between events in memory. In particular, temporal distinctiveness models predict that the temporal position of items prior to the to-be-remembered material will influence memory, while trace decay theory makes no such prediction. While some experiments have begun to look at this issue, evidence for temporal distinctiveness has been mixed, with some supportive evidence (Bright-Paul and Jarrold, 2012), but other studies finding no effect of distinctiveness at least for short-term auditory memory (McKeown and Mercer, 2012; Mercer and McKeown, 2014).

Temporal Isolation Effects

The final source of evidence that we consider for temporal distinctiveness models concerns temporal isolation effects. A key prediction of temporal distinctiveness models is that items that are temporally isolated at presentation (i.e., that are surrounded by large temporal gaps at the time of learning) should be better recalled. The prediction is that such items will be more easily recalled because they are less confusable with their immediate neighbors. While it is not possible to review the several dozen experiments that have examined the issue, the conclusions that have been reached to date depend on the nature of the memory task that is being used and on whether the presentation schedules are predictable or unpredictable.

The basic methodology involves varying the rate of presentation in such a way that some items are more temporally isolated than others. Presentations may be either predictable or unpredictable. Most early experiments examined memory for serial order, usually of verbal material, as the recall task. Several early studies using predictable presentation schedules found an advantage for items in less temporally crowded regions of the list, suggesting that the temporal isolation of items, not just their positions in the list, influence recall (e.g., Neath and Crowder, 1990). Several subsequent studies of forward serial recall found that the apparent effect of temporal isolation disappears when random schedules of presentation are used, but the most recent studies of serial recall have found that, even with random presentation schedules, effects of temporal isolation can be obtained in serial order memory tasks when the task demands encourage representation along a temporal dimension, as, for example, when order of report is unconstrained (Lewandowsky et al., 2008). Temporal isolation effects have been found in running memory tasks when list length is unpredictable (Geiger and Lewandowsky, 2008) and in recognition and free recall tasks (Morin et al., 2010), although Polyn et al. (2014) found, using longer temporal items than did Morin et al., that temporally isolated items were *less* well remembered in a free recall task and suggested that the Morin et al.'s finding represented stronger encoding, rather than enhanced retrieval of temporally isolated items. Most of these experiments have studied memory for verbal material; studies of memory for nonverbal material have sometimes found temporal isolation effects (e.g., Guérard et al., 2010; Shipstead and Engle, 2013) and sometimes not (e.g., Parmentier et al., 2006). Thus the evidence for temporal isolation effects is mixed, and those that have been observed in serial recall maybe due to effects of grouping rather than temporal isolation per se (Farrell et al., 2011). Indeed Farrell (2012) shows with a temporal clustering model that isolation effects in serial and free recall can emerge without the assumption of temporal distinctiveness.

In summary, while reliable temporal isolation effects do seem to be observed under some circumstances, their appearance across a range of memory tasks is far from robust and, when they do occur, alternative theoretical accounts may be

possible. Thus, while further research is needed, temporal isolation effects do not at present offer unequivocal support for temporal distinctiveness models.

Wider Theoretical Implications

We have already discussed how the claims of temporal distinctiveness models relate to the classic debate concerning the causes of forgetting – Is information loss from memory due to trace decay or interference? A closely related question is whether it is necessary to assume a distinction between separate short-term memory and long-term memory systems.

Long-Term Memory and Short-Term Memory

Some temporal distinctiveness approaches to memory, and indeed other temporal contextual models such as the temporal context model (TCM; Howard and Kahana, 2002), emphasize the similarity of memory processes that occur over many different timescales, both the short-term and the long-term. This perspective contrasts with the conventional assumption of a distinction between short-term memory and long-term memory. Specifically, both the retrieved context models, such as TCM, and temporal ratio models, such as SIMPLE, deny the need to assume a separate short-term memory system.

Although the claim that an short-term memory/long-term memory distinction is not required is controversial (e.g., Davelaar et al., 2005), a number of key sources of evidence for the distinction between short-term memory and long-term memory can be captured by some temporal distinctiveness models. We illustrated above how an extended ratio-rule model can simultaneously account for the primacy and delay-sensitive recency effects that have been taken as a signature of a separate short-term memory stem. Neuropsychological data (e.g., from patients with hippocampal amnesia), which have been taken as another source of evidence for an short-term memory/long-term memory distinction, can also be accounted for by a unitary temporal distinctiveness model when patterns of rehearsal are taken into account (Brown et al., 2007a; Dewar et al., 2011). As shown above, temporal distinctiveness models demonstrate that forgetting due to the passage of time alone need not in itself reflect a trace decay process of the type that might be taken to motivate separate memory stores each with their own characteristic cause of forgetting. As we also noted, however, there is still debate as to whether forgetting occurs due to the passage of time alone when temporal distinctiveness is taken into account.

Moreover, claims that a unitary account of memory may be possible fit well with a large body of emerging evidence suggesting that the same variables influence short-term memory and long-term memory tasks when factors such as rehearsal and methodological differences are taken into account (e.g., Tan and Ward, 2000; Ward et al., 2010). In summary, although much more research is necessary, the argument against separate short-term memory and long-term memory systems remains an important claim associated with temporal distinctiveness models.

Consolidation

A final theoretical issue concerns the importance of *consolidation* in memory. According to temporal distinctiveness models of memory, the sole cause of forgetting is interference. How does this claim sit with recent research arguing for the importance of a consolidation process in memory and forgetting? According to consolidation theories, memory representations become stronger, in the sense of being more resistant to forgetting, over time. As noted by Wixted (2004), consolidation processes have been central to theories of memory and forgetting within neuroscience but have seen relatively little application in cognitive models of memory. One of the key direct sources of evidence for consolidation, at least over the short-term, is the observation that an unfilled period of time following the formation of a memory leads to reduced forgetting. According to consolidation theories, the unfilled temporal interval leads to a stronger memory because consolidation processes are uninterrupted. However, the same effect is predicted by temporal distinctiveness models, but for a different reason. Specifically, the addition of an unfilled temporal interval following an event that must be remembered will make the item more temporally isolated, and hence superior memory for that item may reflect not consolidation but temporal isolation. Although there are many data (e.g., on processes happening during sleep) that have not yet been addressed by temporal distinctiveness models of memory, it has been argued that temporal distinctiveness offers an alternative explanation, not involving consolidation, on one of the key behavioral pieces of evidence for consolidation (Brown and Lewandowsky, 2010; Lewandowsky et al., 2012). Thus arguments for consolidation processes must ensure that alternative explanations in terms of temporal distinctiveness can be excluded.

Summary

In summary, we have shown how temporal distinctiveness models assume that memory is temporally organized and that items that occupy nearby temporal locations will tend to be confusable with one another and hence more difficult to retrieve from memory. We have also suggested that temporal distinctive models offer a new theoretical perspective on the causes of forgetting, showing how the fact of forgetting due to the passage of time alone does not necessarily implicate trace decay processes. Along with retrieved temporal content models, temporal distinctiveness models typically (although not always) deny the need to assume a separate short-term memory system.

Abstract

The temporal lobe is one of the four major divisions of the cerebral cortex. The function of the temporal lobe is to transform visual, auditory, and gustatory sensory input into higher-order perceptions and memory. Temporal lobe injury leads to a complex set of symptoms of both basic perceptual processes as well as higher-order processes such as memory and emotion.

Introduction

The cerebral hemispheres can be grossly divided into four lobes (frontal, parietal, occipital, and temporal) that are largely defined by the cranial bone lying above them. The temporal lobes comprise all the tissue that lies below the lateral (Sylvian) fissure and anterior to the occipital lobe, including the limbic cortex on the medial surface of the temporal lobe (Figure 1). The temporal lobe also includes subcortical structures, including the amygdala and hippocampus and their associated cortical regions. This is a large volume of brain tissue that has multiple functions, including the processing of auditory, visual, and gustatory sensations, visuospatial information, aspects of emotion, and certain forms of memory.

Temporal Lobe Anatomy

The human temporal regions can be divided on the lateral surface into those that are auditory (Brodmann's areas 41, 42, and 22 in Figure 1(b)) and those that form the ventral visual stream on the lateral temporal lobe (areas 20, 21, 37, and 38 in Figure 1(b)). The visual regions are often referred to as *inferotemporal cortex* or by von Economo's designation, TE.

The temporal sulci enfold a lot of cortex. In particular, the lateral (Sylvian) fissure contains tissue forming the *insula*, which includes the gustatory cortex as well as the auditory cortex.

The superior temporal sulcus (STS) separates the superior and middle temporal gyri and houses a significant amount of neocortex as well, as illustrated for the rhesus monkey in Figure 2, including many subregions of multimodal cortex that receive input from auditory, visual, and somatic regions as well as from prefrontal and posterior parietal regions.

The medial temporal region includes the amygdala and adjacent cortex (uncus), the hippocampus and surrounding cortex (subiculum, entorhinal cortex, perirhinal cortex), and the fusiform gyrus (*see* Hippocampus and Related Structures).

The cortical region lying along the boundary of the temporal and parietal lobes is often called the *temporal–parietal junction* (*TPJ*). This abstract label refers roughly to the region at the end of the Sylvian fissure, including the ventral regions of the angular and supramarginal gyri (*see* Parietal Lobe) and adjacent temporal cortex. The TPJ is consistently shown to be

Figure 1 Gross anatomy of the temporal lobe. (a) Three major temporal lobe gyri are visible on its lateral surface. (b) Brodmann's areas on the lateral surface, where auditory areas are shown in yellow and visual areas in purple. Areas 20, 21, 37, and 38, the inferotemporal cortex, are often referred to as TE. (c) The temporal lobe gyri visible in a medial view. The uncus is the anterior extension of the hippocampal formation. Reproduced from Kolb, B., Whishaw, I.Q., 2015. Fundamentals of Human Neuropsychology, seventh ed. Worth, New York.

Afferent connections and architectonics of the superior temporal sulcus and surrounding cortex in rhesus monkey. Brain Research 149, 1–24. Adapted from Kolb, B., Whishaw, I.Q., 2009. Fundamentals of Human Neuropsychology, third ed. Freeman, New York.

active in neuroimaging studies investigating attention, memory, language, and social processing. Thus, the TPJ is proposed as central to decision-making in a social context.

Functions of the Temporal Lobe

We can identify five general functions of the temporal lobe: (1) processing of auditory input, (2) processing of visual input, (3) processing of gustatory input, (4) long-term storage of sensory input (memory), and (5) emotional regulation.

Processing of Auditory Input

Sound waves reaching the ear stimulate a cascade of mechanical and neural events – in the cochlea, brainstem, and, eventually, the auditory cortex – that result in a percept of sound. The auditory cortex has multiple regions, each having a tonotopic map. The precise functions of these maps are poorly understood, but the ultimate goal is to perceive sound-making objects, locate sound, and make movements in relation to sound.

Cells in the primary auditory cortex of mammals (Brodmann's area 41, **Figure 1**) respond to distinct frequencies of sound, whereas cells in higher auditory cortical regions respond more to combinations of frequencies. In humans, there is another type of distinction as well. Specifically, two fundamental characteristics of sound are its frequency (spectral feature of sound) and timing (temporal feature). Thus, sounds vary in their frequencies as well as in how quickly they change. In a seminal paper, Zatorre and Belin (2001) demonstrated using positron emission tomography imaging that the primary auditory cortex in both hemispheres responds to temporal features and the higher areas responded to spectral features, but the higher auditory regions showed an asymmetry: the left was weighted toward temporal processing and the right toward spectral processing. There is considerable evidence that the analysis of speech requires rapid auditory processing (i.e., temporal features), whereas analysis of tonal information, such as music, requires the identification of changes in pitch (i.e., spectral features).

Both speech and musical perception require more than just moment-to-moment analysis of temporal and spectral features, but there is also a memory component referred to as echoic memory. Echoic memory is crucial for auditory perception, because the meaning of any single sound depends upon the following sounds. Although the precise length of echoic memory is variable, it generally lasts about 3–4 s though some authors have shown it to last up to 20 s. Echoic memory appears to involve an extended network of cortical regions, but a key region is the superior temporal gyrus (e.g., Alain et al., 1998).

Processing of Visual Input

The occipital lobe sends a major projection to multiple regions in the temporal cortex both in the middle and ventral temporal gyri (inferotemporal areas labeled TE in **Figure 2**), as well as the anterior tip of the superior temporal gyrus and the STS. The posterior parietal lobe sends connections to the medial temporal regions (hippocampus and parahippocampal regions).

Neurons in the inferotemporal cortex are tuned for the features of objects and faces and many change their pattern of firing with experience, including how often a visual stimulus has been encountered and any association with reward. These properties make the ventral stream more tuned to the enduring characteristics of visual stimuli than with the moment-to-moment changes in the visual array, which provides a basis for object recognition.

Another characteristic of inferotemporal neurons is that they provide a mechanism for the internal representation of images of objects. Fuster and Jervey (1982) first demonstrated that, if monkeys are shown specific objects that are to be remembered, neurons in the monkey cortex continue to discharge during the 'memory' period. These selective neuronal discharges may provide the basis of working memory for the visual stimuli (sometimes referred to as iconic memory). Furthermore, these discharges may provide the basis for visual imagery. That is, the discharge of groups of neurons selective for characteristics of particular objects may provide mental images of those objects in their absence.

Regions of the ventral stream have surprisingly selective tuning to specific stimulus characteristics such as specific body parts (hands, bodies, faces), color, or scenes. One example is a region in the fusiform gyrus, the fusiform face area, which is selectively activated by faces (e.g., Kanwisher, 2010). Another is a more medial region in the hippocampal gyrus, the parahippocampal place area, which is preferentially active for scenes including buildings and places. This region is hypothesized to play a significant role in visuospatial navigation, reflected both in the specificity of activation to scenes as well as the input from the posterior parietal regions involved in directing movements in space (*see* Parietal Lobe; Cortical Areas Engaged in Movement: Neuroimaging Methods).

A different type of visual analysis is performed by the STS. The STS receives multimodal inputs that play a role in categorizing stimuli. A major category is social perception, which includes analyzing actual or implied body movements (biological motion) that provide socially relevant information. This information plays an important role in social cognition, a 'theory of mind' that allows us to develop hypotheses about other people's intentions. For example, the direction of a person's gaze provides us considerable information about what that person is – or is not – attending to. Many cells in the STS are especially tuned to faces, including the precise orientation (e.g., head-on, profile) as well as specific facial expressions. Some cells in the STS are maximally sensitive to primate bodies moving in a particular direction, which is remarkable because the basic configuration of the stimulus is identical as the body moves in different directions; only the direction changes (see review by Barraclough and Perrett, 2011).

Processing of Gustatory Input

The primary taste cortex is found in the insula (*see* Taste and Smell, Psychology of). The insula contains neurons tuned to the five basic tastes (sweet, salt, bitter, sour, and unami) as well as other neurons that encode oral somatosensory stimuli (viscosity, fat texture, temperature, and capsacin). Thus, our perception of taste is not just the basic tastes but also an interaction of the taste and texture of food. Human imaging studies using MRI have shown that insular activity correlates with the subjective intensity of tastes.

The insula projects to the orbitofrontal cortex, which is likely the secondary taste area. Activation of the orbitofrontal cortex correlates with the subjective pleasantness of taste rather than the intensity (*see* Taste and Smell, Psychology of).

Memory

Interest in the temporal lobes' function in memory was stimulated in the early 1950s by the discovery that bilateral removal of the medial temporal lobes, including the hippocampus and amygdala, results in amnesia for all events after the surgery (anterograde amnesia). It is now clear that both the medial temporal regions play a central role in the extended neural circuitry underlying explicit memory. The key structures are the hippocampus, entorhinal cortex, perirhinal cortex, and parahippocampal cortex (Petri and Mishkin, 1994). Although it is not possible to distinguish the roles of these regions in humans, studies in monkeys are providing some insights. The perirhinal cortex appears to support memory for objects (including factual knowledge about the world), whereas of the hippocampus and parahippocampal regions, the hippocampal regions are central to the circuits underlying contextual knowledge (autobiographic, or episodic, knowledge).

The amygdala also plays a role in memory, but is involved in a circuit underlying emotional memory. The amygdala has close connections with other medial temporal structures as well as the frontal lobe. It also sends projections to the brainstem structures that control autonomic responses such as blood pressure and heart rate, the hypothalamus that controls hormonal systems, and the periaqueductal gray matter that affects the perception of pain.

Emotional memory has been studied most thoroughly in fear conditioning (*see* Fear Conditioning: Overview). The amygdala seems to evoke our feelings of fear/anxiety toward stimuli that are threatening, but also can do the same toward stimuli that by themselves would not normally produce fear, such as is observed in anxiety disorders.

Emotional Regulation

An interconnected network of structures including the neocortex, thalamus, hippocampal formation, and amygdala forms the basis of emotional experience (*see* Emotion, Neural Basis of). The amygdala receives input from all of the sensory systems. The amygdala can therefore create a complex image of the sensory world. To be excited, cells in the amygdala require complex stimuli such as faces. Thus, like the STS, the amygdala plays a role in identifying facial expressions. As noted earlier, the amygdala also interacts with brainstem structures that control autonomic responses and thus can link external stimuli with emotional feelings.

Symptoms of Temporal Lobe Injury

Nine principal symptoms are associated with disease of the temporal lobes: (1) disturbance of auditory sensation and perception, (2) disorders of music perception, (3) disorders of visual perception, (4) disturbance in the selection of visual and auditory input, (5) impaired organization and categorization of sensory input, (6) inability to use contextual information, (7) impaired long-term memory, (8) altered personality and affective behavior, and (9) altered sexual behavior (Kolb and Whishaw, 2015).

In contrast to damage in the primary visual or somatic regions, bilateral damage to the primary auditory cortex does not produce a complex loss of sensation (auditory deafness). Rather, damage to auditory cortex impairs the processing of speech sounds (left hemisphere) or in making pitch discriminations (right hemisphere). These deficits are consistent with the observation of aphasia in patients with large injuries of the left temporal regions including both the primary and secondary auditory regions, including Wernicke's area. In contrast, damage to the superior temporal gyrus on the right disrupts the processing of musical sounds, the exact deficit depending upon the site of injury. For example, rhythm discrimination is most affected by right posterior superior temporal gyrus damage, whereas meter discrimination (for example, distinguishing a waltz and a march) is more affected by anterior damage to either temporal lobe.

People with inferotemporal cortex injuries do not have field defects such as those with occipital lesions, but they do have deficits in the perception of complex scenes, reflecting the role of the inferotemporal cortex in the ventral stream of visual processing. Recall that neurons in TE show selective tuning to specific object characteristics so it is not surprising that temporal lesions would interfere with perceiving these characteristics and may produce specific visual agnosias.

Persons with temporal lobe damage frequently report difficulties in attention to auditory or visual information when there are multiple competing inputs. For example, if two

people are talking at once we usually can shift from listening to one and then the other. Temporal lobe patients have great difficulty in doing this and as a result get little from either speaker. Similarly, one strategy that we unconsciously use for understanding visual and auditory material is to categorize it. When asked to learn a list of words such as 'dog, car, bus, apple, rat, lemon, cat, truck, orange,' most of us will organize the words into three different categories – animals, vehicles, and fruit. If the list is later recalled, the items are likely to be recalled by category, and recall of the categories is likely to be used as an aid in recalling the items. Patients with temporal lobe injuries do not do this, leading to less efficient perception and memory of the information.

Context plays an important role in normal perception and recall of sensory information. Seeing a familiar object or person in a novel context can often give us pause to identification. For example, encountering a clerk from your neighborhood store on a bus in Stockholm may provoke a feeling of familiarity but because the context is wrong, identification of the person is likely to be slow. It is clear that we use normally context as a cue in object identification. Patients with temporal lobe injuries are impaired at this ability, giving rise to both perceptual and memory difficulties.

But memory deficits are larger than just those related to context. Temporal lobe injuries, especially those involving medial temporal lobe structures, can result in amnesia both for events preceding the injury (retrograde amnesia) as well as for events following the injury (anterograde amnesia) (*see* Amnesia: General; Declarative Memory, Neural Basis of).

Finally, temporal lobe injury, especially when the amygdala is damaged, can produce profound changes in personality. Bilateral amygdala damage is associated with a loss of emotion, and especially fear. The general clinical impression is that temporal lobe patients have a clear personality change, sometimes referred to as a temporal lobe personality (e.g., Bear and Fedio, 1977). Symptoms include increased emotionality, depression, obsessionalism, religiosity, paranoia, and a reduced sense of humor.

Conclusion

In summary, the temporal lobe plays a central role in the higher-order analysis of auditory and visual information, and especially in context. As a result, temporal lobe injury leads to a complex set of symptoms of both basic perceptual processes as well as higher-order processes such as memory and emotion.

Tense, Aspect, Mood and Evidentiality, Linguistics of

Östen Dahl, Stockholm University, Stockholm, Sweden

Abstract

Together tense, aspect, mood, and evidentiality, or TAME for short, play a central role in the grammars of most languages in the world. They are typically marked inflectionally on verbs but can also be expressed by derivational morphology and by periphrastic constructions. Although tense, aspect, and mood, and sometimes also evidentiality are traditionally treated as separate grammatical categories, they are intertwined in TAME systems in ways that make it difficult to uphold such a treatment.

Introduction

The English sentences *He is asleep* and *He was asleep* differ in tense: the former is in the present and the latter in the past tense. In a similar way, *She opened the window* and *She was opening the window* are said to differ in aspect, and the verbs *wish* and *were* in the sentence *I wish I were dead* are said to differ in mood. In the grammatical tradition inherited from Latin grammar, verbs are said to possess the inflectional categories of tense and mood, and aspect was added to them later on, partly due to influence from the study of Slavic languages. In recent years, it has been proposed that evidentiality, defined as the grammatical marking of information source, should be recognized as a grammatical category distinct from tense, aspect, and mood. Together tense, aspect, mood, and evidentiality, or TAME for short, play a central role in the grammars of most languages in the world. It should be noted from the outset, however, that tense, aspect, mood, and evidentiality do not usually come neatly lined up as separate categories in grammars. Rather, the meanings of TAME forms often combine elements from more than one of them. Conversely, distinctions that would traditionally be thought of as belonging to the same category may be expressed in very different ways, for instance, by inflectional forms on the one hand and auxiliary constructions on the other. For this reason, many linguists prefer to see TAME as one large domain within which various grammatical distinctions may arise.

In traditional grammar, tenses and moods are inflections on the main verb of a sentence. Inflectional TAME can indeed be seen as the central and most typical case, but TAME can also be realized periphrastically, that is, by a construction involving more than one word, the grammatical markers being either auxiliaries or indeclinable particles.

General works on TAME include Comrie (1976, 1985) and Binnick (1991, 2011). Two early works that have had a particularly strong influence on the study of TAME, although their authors were philosophers rather than linguists, are those of Reichenbach (1947) and Vendler (1957). Important monographs are also those of Klein (1994) and Smith (1991).

TAME and Finiteness

TAME is intimately linked up with the notion of finiteness in grammar. Finiteness is a property that characterizes main clauses such as *She opened the window* and subordinate clauses such as (*I saw that*) *she opened the window* as opposed to other embedded, nonfinite constructions such as (*I saw*) *her open the window* or (*It is forbidden*) *to open the window*. In English and many other languages, TAME is fully realized only in finite clauses, while it is restricted or absent in nonfinite clauses. The term 'tensed clause' has sometimes been used in the same sense as 'finite clause.' For a collection of articles on finiteness, see Nikolaeva (2007).

The Typology and Diachrony of TAME

Typologically oriented works by Dahl (1985) and Bybee et al. (1994) have shown that although there is great variation among languages as to their TAME systems, the elements of those systems may be reduced to a relatively small number of types, each with its characteristic meaning and typical way of expression, developing historically by processes of grammaticalization. Such processes usually start with phrasal constructions involving lexical morphemes. Future markers may, e.g., develop out of constructions involving motion verbs such as 'come' and 'go,' or modal verbs with the meanings of obligation ('shall, must') and volition ('want'). Later on, inflections may arise through the coalescence of earlier free morphemes (auxiliaries or particles) with the stem of the main verb. The elements of a TAME system in a language may be at different stages in these grammaticalization processes; how far they have advanced determines both their form and their meaning. Thus, only a few of the types described below typically show up in inflectional distinctions, while the others tend to be expressed periphrastically.

Another finding of recent typologically oriented work is that there are some fairly strong areal tendencies in the makeup of TAME systems (Dahl and Velupillai 2011a,b,c,d,e; de Haan 2011a,b). Most notably perhaps, the distinction between past and nonpast is represented in virtually all languages in a large area stretching from Iceland in the northwest to the Horn of Africa in the south and Bangladesh in the southeast, including much of Central Eurasia (but excluding northeastern Siberia). It includes not only Indo-European languages but also languages from the Uralic, Altaic, and Afro-Asiatic families and some language isolates.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.52025-X

Tense

The basis for the distinctions between forms traditionally subsumed under the category of tense is the time dependence that characterizes the overwhelming majority of statements in natural languages. A sentence such as The *baby was asleep* does not make very much sense as long as we do not know what time we are talking about – that is, at what time the baby was asleep. In English, the tense of the verb gives us some indication about the time – we know that the speaker is referring to some point in the past. However, the exact location of that point is not indicated explicitly and has to be retrieved from the context. In many languages, e.g., Chinese, no distinction would be made between *was asleep* and *is asleep* here – in those languages, the identification of the 'topic time' or 'reference time' is left wholly implicit. Nevertheless, the identification has to be made, in order to make sense of the statement. Thus, the way in which sentences are interpreted is similar whether or not a language makes the grammatical distinction between present and past tense. Note also that tenses are not complementary to time adverbials, as is often assumed. Languages that lack tense distinctions do not, on the whole, use time adverbials more often than languages that do not. This is because time adverbials are used whenever the contextual temporal information is insufficient. Tenses, on the other hand, being more or less obligatory grammatical elements, are used whether or not the information they contain is necessary for the communication.

In the most straightforward cases, the choice of tense depends on the relationship between the topic time and the time of speech. Time as experienced by a person is naturally divided into present, past, and future; these are also the three basic tenses of traditional grammar, although it is common for languages to have only a simpler, two-way distinction in their grammar: either between past and nonpast or between future and nonfuture. In English, only the past tense (*he called*) differs from the present (*he calls*) morphologically; what is traditionally referred to as the future (*he will call*) is an auxiliary construction, although inflectional futures are far from uncommon in other languages (e.g., French *il dormira* 'he will sleep'). It is common for languages to have several ways of marking the future grammatically, often differing in subtle modal nuances (cf English *will* vs *is going to*). The common modal coloring of future tenses has led many scholars to deny the future status as a tense, but it is clear that temporal considerations are also part of the semantics of future tenses, and the mixture of temporal and modal criteria should rather be seen as typical of TAME in general.

Many languages distinguish grammatically degrees of remoteness in the past and sometimes also in the future. This means that different grammatical forms are used for recent and remote events. The distinctions may be more objective, that is, depend on units such as days or (less often) years, or more subjective, that is, depend on the speaker's assessment of an event as recent and remote. Commonly, objective and subjective criteria are combined in one and the same system. A typical system of remoteness distinctions in the past could include a 'hodiernal' past, for events earlier today, a 'hesternal' past, for events yesterday and possibly a few days back, and a 'remote' past, for events further back in time. Remoteness distinctions are found in TAME systems all over the world, but are most common in certain areas, notably sub-Saharan Africa, New Guinea, and Amazonia.

A distinction is customarily made between absolute and relative tense, depending on whether the point of departure is the time of speech or some other time point. The tenses of finite verbs in main clauses are usually absolute – past tense means that the topic time precedes the time of speech. Nonfinite verb forms such as participles, gerunds, and infinitives sometimes also show tense distinctions, but these predominantly mark relations of simultaneity or temporal sequence relative to the time of the next higher finite verb, as in the sentence *She lived in London, working for a large company* where the gerundial clause is understood as being about the same time as the main clause (which, in its turn, is understood as preceding the point of speech). Finite verbs in subordinate clauses may follow varying principles. In clauses expressing reported speech, the verb is in many languages in the same tense as it would have in a direct quote; in English and some other European languages, the tense of such clauses depends on the tense of the matrix main clause. This phenomenon, exemplified in a sentence such as *John said that he was ill* (cf *John said "I am ill"*), is traditionally referred to as 'sequence of tenses'; there is disagreement among scholars about its nature.

In some languages, special narrative tenses are used to express an event that takes place directly after another.

Aspect

Whereas the notions underlying the distinctions subsumed under tense are relatively straightforward, aspect is a more elusive notion. It is natural to see the sentences we utter as describing or evoking entities such as events, processes, and states. There is no word in everyday English that covers all these, but scholars use terms such as 'situations' and 'eventualities' when they generalize over them. Clearly, verbs and verb phrases (let us call them 'predicates' for short) differ in what kinds of entities they most naturally evoke. For instance, *Mary woke up* is about an event, whereas *Mary slept* is rather a state. Several ways of classifying predicates according to such criteria have been proposed. One such classification would distinguish stative predications from dynamic ones depending on whether they involve some kind of change or not. Thus, *sleep* would be stative, whereas *wake up* would be dynamic. Among dynamic predications one can distinguish telic and atelic predications, where telicity involves the presence of a boundary or the attainment of a specific result-state: *bake* would be atelic and *bake a cake* telic (since it involves the coming into existence of a cake). Telic predications can then be classified into punctual and nonpunctual or durative depending on whether the situations/eventualities are seen as having duration or not.

According to a popular view, grammatical aspect involves the choice of a perspective or viewpoint on a situation/eventuality, but an alternative analysis sees aspects as marking the conversion of a predicate from one type to another. The relationship between situation types and aspects is not easy to

disentangle, one reason being that there is seldom a one-to-one relationship between verbs as lexical items and situation types.

In languages that express aspectual distinctions in their inflectional systems, the most common distinction is between perfective and imperfective aspect. According to a common view, perfective aspect views the situation/eventuality in its totality. Imperfective aspect is used for what is going on at the topic time but also for habitually occurring events.

There is a connection between telicity and perfectivity in that telic predications are most naturally given a totality interpretation. But there is a further connection to temporal reference.

Referring to an event in its totality is usually only possible if it has been completed at the time of speech. As a consequence of this, perfective aspect tends to be restricted to past time reference, or at least to nonpresent time reference. Furthermore, telic predications that are not overtly marked for tense or aspect are interpreted as referring to the past in many languages.

These connections between temporal and aspectual notions lie behind the skewings that are typically found in TAME systems, where distinctions between perfective and imperfective aspects are only upheld in forms with past time reference. An example of such a skewed system is found in written French, in which perfective aspect is represented by the so-called passé simple or simple past (*il chanta* 'he sang'), while the present (*il chante* 'he sings/is singing'), the imparfait or imperfective past (*il chantait* 'he sang/was singing'), and the future (*il chantera* 'he will sing') represent combinations of the imperfective aspect with various tenses.

Aspect may also be expressed by periphrastic or derivational means. Progressives, as exemplified by the English construction *I am/was/will be singing*, are a common type in languages and tend to be expressed periphrastically. With regard to their meaning, they resemble imperfective aspect but have a more restricted domain of use in that they are only marginally used about states or habitual events. Historically, progressives are a common source of imperfectives.

Special habitual inflections or periphrastic habitual constructions are not uncommon; these may be used for events that take place regularly (*I used to visit her on Sundays*) but sometimes also for generic statements such as *Dogs bark*.

In many languages, the aspectual character of verbs may be modified by derivational processes. In contradistinction to inflectional aspect, these processes tend to be idiosyncratic and restricted to smaller sets of lexical items. They also more clearly involve conversion from one type of situation/eventuality to another. A typical distinction expressed by derivational aspect is that between semelfactive or punctual, on one hand, and durative on the other, as in Hungarian *köhintett* 'he coughed once': *köhögött* 'he coughed (for a longer or shorter time).' The famous aspectual systems of Russian and other Slavic languages are derivational in origin but have over time been regularized and received many features that make them seem more like inflectional aspect.

The Perfect

The English perfect, as in *He has sung*, represents a cross-linguistically common type the semantics of which defies the traditional classification in that it cannot be unambiguously subsumed under either tense or aspect. Perfects are used of events that took place in the past but have a more restricted domain of use than ordinary past tenses. A common way of formulating the meaning of perfects is to say that they imply 'current relevance' of the event related in the sentence. Another way of putting this is to make a distinction between the 'time of event' and the 'topic time' (or reference time): in the perfect, the time of event is in the past but the topic time is equal to the time of speech. In the pluperfect (e.g., *He had sung when I arrived*) the time of event also precedes the topic time but here both points are in the past. In a future perfect, the topic time is in the future and the time of event precedes it, as in *He will have sung when I arrive*.

Within the semantic domain typically covered by perfects, we also find more specialized forms and constructions. Resultatives express the resulting state of some event (e.g., *He is gone* in English); they are usually restricted to verbs that denote change. Historically, they are often extended in meaning to become perfects. Experientials, such as the Japanese *koto ga aru* construction (*Nihon de hataraita koto ga aru* "I have worked in Japan") are used to express that some type of event took place one or more times within a period in the past.

Mood

There is some terminological confusion about the terms 'mood' and 'modality,' but commonly, the latter is taken to refer to a broad semantic domain having to do with the relationship between a proposition and reality, involving e.g., notions such as necessity, possibility, and probability. In English, modality is typically expressed by modal auxiliaries such as *can*, *may*, and *must*, or adverbs such as *perhaps*. Mood, on the other hand, is traditionally a narrower notion, referring to grammatical distinctions, which, like TAME in general, tend to be expressed by inflections of verbs. Moods are commonly said to express the speaker's attitude to a proposition or to its truth-value. However, more often than not, the speaker is not free to choose between moods, but the choice is governed by the type of clause or by the syntactic environment. A typical grammatical mood, such as the subjunctive in English, French, or German, is thus used to mark certain nonasserted and grammatically subordinate clause types. Thus, in French, the subjunctive is obligatory in the complement clauses of verbs meaning 'want, desire, hope.' The subjunctive thus marks these clauses off against plain main clauses, which are the unmarked, indicative mood: *Il est parti* 'He has left' with the indicative versus *J'espère qu'il soit parti* "I hope that he has left," with the subjunctive. In German, both these examples would be translated with the indicative. On the other hand, the subjunctive is used in German in clauses expressing indirect speech, which is not the case in French. Thus, nonindicative moods vary cross-linguistically as to their specific functions, although they share the property that they occur in clause types that are typically not used to make an assertion. Furthermore, a language may have more than one nonindicative mood. Thus, Classical Greek had both subjunctive and optative moods with different nonassertive uses.

Another common function of nonindicative moods is to distinguish between possible and counterfactual situations in conditional constructions (cf *If he is ready, we can go* vs *If he*

were ready, we could go, where the latter sentence contains the obsolescent subjunctive form *were*). A form usually subsumed under mood is the imperative, whose primary use is to express speech acts such as commands, requests, etc. However, it can be argued that imperatives should be regarded as representing a separate dimension, not subsumable under mood. In many languages, particularly in the large Austronesian family, there are verb forms, which combine uses as a future tense with uses typical of nonindicative moods. These are commonly referred to as irrealis forms and are then opposed to realis forms, which correspond to present and past indicative forms in other languages. It should be noted, however, that similarly to non-indicative moods, irrealis forms vary widely with respect to the specific functions they have.

Evidentiality

Evidentiality is customarily defined as the grammatical marking of source of information (Aikhenvald, 2004). Grammaticalized evidentiality marking tends to always reflect a basic distinction between direct ('witnessed') and indirect ('non-witnessed') information sources, where the former notion is understood as meaning that the speaker has sensory evidence for the content of the sentence.

The types of indirect information that are most commonly relevant in TAME systems are (1) inference and (2) second-hand or quotative information (i.e., information obtained from another person). These can be marked separately or by a common marker. Many languages restrict evidentiality markings to past time reference. A standard example of a language with a grammaticalized evidentiality distinction is Turkish, where 'Ahmet came/has come' could be expressed either as *Ahmet gel-di* or as *Ahmet gel-miş*, where the suffix –di is used when the speaker has witnessed the coming, whereas the suffix *-miş* is used when the speaker has inferred or learnt from someone else that Ahmet has come. The TAME systems of most European languages are at most marginally sensitive to evidentiality distinctions, which may explain why evidentiality has not been given due attention in earlier work, although it is a common feature in the languages of all other continents except Africa. Complex evidentiality systems are found in many South American languages.

Territorial Conflicts

Abstract

This article begins with a review of historical sociological work on the linked origins of territory, organized violence, and political power. It then surveys the large-n studies on territorial conflict that search for correlations between territorial disputes and the incidence of interstate war. It examines recent disaggregated approaches to the study of territory and conflict before outlining the contributions of the rich case study literature to our understanding of territorial conflict. It analyzes the nexus of territory, technology, and conflict and concludes with a discussion of new theoretical approaches to territoriality, power, and conflict.

Introduction

The fact that almost all competitive team sports present minor variations on the same stylized contest over the control of territory is just one everyday reminder of the deeply rooted relationship between the social phenomena of territory and conflict. The penetration of the deepest part of the opponent's territory that is achieved when a goal or try or basket is scored is one of the simplest and most powerful symbols of victory yet devised. Territorial domination provides unambiguous evidence of domination in general. It has a simplicity that ensures that the symbol can travel easily across linguistic and political borders. Recent decades have seen major advances in social scientific theorizations that analyze territory at a fundamental level, as a core constitutive dimension of conflict of all kinds, a source of power, and a strategy for exerting power. Territory is characterized in this article as a socially constructed phenomenon that takes various historically specific forms but that nonetheless retains certain key characteristics that ensure that it remains a central focus for conflict and violent contestation. The article begins and ends with discussion of theoretical approaches to territory and conflict.

Much contemporary work on territorial conflict has a rather narrow focus however, concentrating on relations between sovereign states, and in particular, on disputes over interstate boundaries. This article reviews this strongly quantitative tradition in the study of territorial conflict, outlining the key questions asked, and the methodologies used. It outlines the key findings of the work on interstate conflict and looks at the way in which similar methodologies and datasets have been deployed to understand territorial contestation within states – by secessionist movements and ethnonational minorities.

More recently, there have been major innovations in the study of territory and conflict based on the geographical disaggregation of violent conflict. Recent studies have moved away from the dominant approaches in which the nation-state as a whole was treated as the key unit of measurement and effectively as the sole meaningful territorial context for explaining violent conflict. Large-scale databases of violence that have been geographically disaggregated to very small localized blocks of space, illustrate starkly the fact that violent conflict is very unevenly distributed within states. At the same time micro-level qualitative research on conflict, much of it by sociologists and anthropologists, has greatly advanced our understanding of the significance of boundaries and territories other than those of the nation-state. Zones of control, informal ethnonational residential boundaries, and administrative and linguistic territories, all help to shape and structure patterns of conflict and act often as a focus for violence.

The article examines the changing character of territorial conflict in an age of rapidly developing information and communication technologies. Remote-controlled technologies for territorial penetration and surveillance, technologies permitting direct communication with civilians in 'enemy' territory, and GPS technologies that permit the deployment of intensely spatially concentrated violence at huge distances unsettle long-established assumptions and legal frameworks for the management of warfare and violence. How then is territorial conflict changing? To what extent are we seeing a reconfiguration of the relationship between territory and conflict or a severing of the links between the two?

We conclude with a discussion of theories of territory and power that offer a way to analyze the connections between conflict and territory at all scales: at the level of interstate disputes; substate struggles over international borders by nationalist and secessionists; and the informal boundaries of everyday life.

The Sources of Territorial Conflict

Much recent research on territorial conflict has focused on disputes between sovereign states over international borders. However, both the sovereign nation-state and strongly institutionalized interstate boundaries are relatively recent phenomena. International border disputes are just one historically specific form of territorial conflict. The work of historical sociologists indicates that territory is not simply one among a multitude of variables that contribute to conflict. They emphasize that territory and organized violence are interdependent and interrelated at the most fundamental level.

In his work on the origins of power Michael Mann (1986) places territoriality at the heart of his explanation for the initial emergence of organized violence more than 5000 years

ago. He uses the metaphor of a gradually intensifying 'caging' of human activity to emphasize the importance of bounding processes in the initial emergence of both states and warfare (1986: 37–40, 45–49). Mann begins by outlining the way in which the initial shift to agriculture intensified the territorialization of social life, sowing the seeds of warfare. Once land had been cultivated and buildings constructed to store the grain surplus from year to year people were tied to specific spaces to a much greater extent than before, tied to their home territories. It became much more important to defend and maintain boundaries as the option of simply moving on elsewhere in the face of violent challenge became much less attractive and feasible. At the same time, the increased fixity of the population created both the opportunity and the need for more elaborate structures of rule and of coercion. These interlinked developments created the conditions for the first time for the emergence of states and the associated organization of violence. States, organized violence, and intensified territoriality emerged together – none of them being possible without the other. Territorially bounded spaces do not just form the backdrop to the organization of violence but are central to the phenomenon of organized violence of all kinds. Without territory there is no warfare.

The work of Tilly (1978) and Giddens (1996) similarly surveys patterns of conflict across the entire globe across huge swathes of time. Both authors illustrate the extent to which interstate boundary disputes in our current relatively stable global system are a historically specific phenomenon – just one of the forms that territorial conflict takes. As Giddens points out, warfare and political violence in the modern era take place within a broader framework of pacification at both national and geopolitical levels and must be understood in the context of long-run historical processes of increasing internal pacification, territorial centralization of power, the growth of state apparatuses, and increasingly clearly drawn international borders. This work places the changing character of territorial control at the heart of our explanations of all forms of organized violence.

Correlating Conflict and Territory

Are territorial disputes more likely to lead to war than other kinds of disputes? Is violence more intense and warfare more prolonged when territory is at stake? Is it really territory that causes war or does an apparent link between territorial disputes and war obscure the importance of adjacency and propinquity? Perhaps neighboring states are much more likely to go to war simply because they interact more and are more likely to have conflicting interests rather than because territory is uniquely contentious. These are the core questions addressed in the extensive large-n literature on territorial conflict that tests tightly defined hypotheses on the causation of war by examining correlations between territorial disputes and warfare in large international datasets.

While some of the work in this tradition argues that proximity or contiguity are the crucial causal factors in increasing the risk of war between two states, most work is dominated by what is called the 'territorial perspective': the argument that territorial disputes play a distinctive part in causing violence. The essential findings of this perspective are that "territorial disputes increase the probability of war and have a higher probability of going to war than other kinds of disputes" (Vasquez and Henehan, 2001: 123). Disputes over territory are more likely to lead to war than 'policy' or 'regime' disputes. The large-n studies treat territory as one variable among many, a variable whose effect can be isolated and whose influence on war, the primary object of inquiry in this literature, can be quantified and compared with that of other variables such as GDP or political system. One of the difficult questions raised by the theoretical literature on territory is whether in fact it is possible to treat such a fundamental constitutive aspect of the political as though it is just one more field to be isolated and defined. This correlative work on territorial conflict is deeply shaped by rational choice models of human behavior, modified to address the symbolic and emotional value that people attach to territory.

Why then should conflicts over territory be more likely to cause war than other conflicts? Surveying this literature, Hensel (2000) identifies three of the reasons why scholars working in this tradition regard territory as important. First, states have straightforwardly rational motivations to want territory because it is a resource valued for its strategic or economic utility. Secondly, territory is important as an idea, powerfully tied up with a sense of national identity and with important emotional aspects of political life. This symbolic dimension of territory often generates strong domestic resistance to compromise on territorial disputes with other states and regimes willing to compromise on territorial issues can experience difficulties in maintaining domestic support. This is what we might call the Field of Blackbirds or Jerusalem argument, given that it has become a commonplace in recent years to illustrate the point by reference to Serb reluctance to relinquish the sites of medieval battles in Kosovo or Israeli insistence on the indivisibility of the holy city of Jerusalem. It is primarily because of the meaning, the emotion, and the symbolism invested in territory that this most divisible of goods can be characterized from a rational choice perspective as indivisible. But this is not necessarily because individuals are hardwired to feel a deep attachment to the national homeland. Acknowledging that emotional and symbolic factors are centrally important in rendering Jerusalem indivisible and hindering a compromise, Goddard (2010) nonetheless argues that there is an instrumentally rational foundation for this indivisibility. She argues that political rhetoric invoking the sacred character of national territory, driven in turn by domestic interparty competition in Israel/Palestine, helped to render Jerusalem indivisible by making it a touchstone issue, thus trapping politicians in their own rhetoric. She contrasts this with the Irish case in which a modification of the Irish nationalist position and rhetoric on the indivisibility of Irish national territory rendered the territory divisible and facilitated territorial compromise.

The third factor identified in these studies is the effect on a state's reputation of yielding in a territorial dispute. States will refuse to compromise on territory in order to protect their reputation, to shape the expectations of other states about how they will behave when challenged and to ensure that they are not seen as weak and vulnerable to pressure. Here too the analysis is saturated with the assumptions of rational choice

theory about the mutually shaping power of both parties' expectations and understandings of the opponent (Schelling, 1960). Presumably territory is such an important factor in reputation both because it is constitutive of the state – a state that loses territory is no longer exactly the same state as it was – and because it provides one of the most unequivocal signs of submission and defeat. Unlike other concessions and compromises, a retreat from territory is particularly difficult to spin as a gain or an achievement of some kind.

While not engaging directly with debates on territory, game theorist Thomas Schelling has quite a bit to say about space and boundaries in his 1960 classic, *Strategy of Conflict*. His analysis of the shaping force of national borders in warfare provides a neat illustration of the way in which both the symbolic power of borders and their role in shaping expectations can powerfully influence the course of a war. Explaining why the United States decided not to cross the Chinese border during the Korean War despite Chinese involvement in the war Schelling writes:

> What makes the Soviet or Chinese border a pertinent or compelling place to draw a line in the event of war in that area is principally that there is usually no other plausible line to draw … there is just no other stopping place that can be tacitly acknowledged by both sides…It has a compelling power of suggestion, a claim to attention, the denial of which might seem … to be a denial of any limitation.
> Schelling 1960[1980]: 259

Schelling highlights the moderating and limiting power of clearly delineated and mutually recognized borders but the point has relevance too for territorial disputes. In highlighting ideas, understandings, and expectations, Schelling provides here a strongly rationalist argument for the importance of the symbolic dimension of boundaries in shaping the pattern and intensity of warfare.

While large-n studies of territorial conflict have focused overwhelmingly on interstate disputes over international borders, some scholars have turned their attention more recently to nationalist and secessionist disputes that are generally characterized as domestic or internal. Duffy-Toft (2003), for example, analyzes the correlations between the level of territorial concentration of minorities and the likelihood of political violence and finds that territorial concentration correlates strongly with high levels of violence.

One of the curious features of this large-n work is that much of it has very little concern with territory itself or even, in many cases, with territorial conflict. The relationship between territory and conflict is often investigated primarily because it provides one of the more straightforward ways in which to test the democratic peace thesis which holds that democracies are less likely to go to war. The likelihood of territorial disputes to cause conflict is investigated in order to determine whether political systems are the key determinant in warfare. In addition, even where this work is mainly focused on identifying the primary causes of conflict it does not tend to be very much concerned with investigating the nature of territory. It is rare for work in this tradition to cite theorists of power and territory such as Gottmann, Sack, Paasi, Raffestin, or Lefebvre. The result is that territory itself is curiously absent from much of this work.

Disaggregating Conflict

One of the weaknesses of the large-n work on territorial conflict is that it is restricted to just one kind of historically specific territory – the nation-state – and just one kind of territorial conflict, disputes over interstate borders, a weakness recognized by some of those working in the field. This is partly the product of the widespread methodological nationalism that treats the nation-state as the primary geographical unit of analysis and has locked much social scientific work into state-bounded frameworks for analysis. Using state territories as part of the framework for the coding and collection of data on territorial conflicts renders other kinds of territories invisible, reifies the distinction between internal and external, and steers analysis toward a relatively narrow set of questions focused on a small subset of territorial conflicts.

There is a radical spatial unevenness to violence in civil wars and other intrastate conflicts that defies explanation at the national level. This variation is almost invisible in datasets that use the state as the main unit of analysis. Civil wars can often be difficult to disentangle from interstate wars and the problem of unevenness also has implications for our understanding of the latter. In virtually all civil wars large swathes of territory remain largely unaffected by violence, and villages only a few miles apart can have sharply contrasting experiences of violence. This unevenness presents a challenge to explanations of conflict that treat states as the primary unit of analysis. If factors at the national-level generate civil war conflict why do they not generate it more evenly across the space of the states concerned? If conflict is radically uneven in its distribution and if contests over territory at the regional and local level are crucial in explaining these uneven patterns it follows that much of the explanation of the relationship between conflict and territory must be located at these same scales. If violence is unevenly distributed, perhaps the explanation for violence lies not with the characteristics of a state as a whole but the characteristics of particular regions or localities, or with spatially and temporally uneven processes in which local territorial frameworks of various kinds decisively shape the escalation and diffusion of violence.

In response to this problem of unexplained unevenness in violence, a range of databases of disaggregated data on incidences of violence have recently been established, and a lively publication program has begun to explore subnational patterns of distribution and diffusion of violence (O'Loughlin and Raleigh, 2008; Raleigh et al., 2010). This new approach is valuable in highlighting the exceptional unevenness of violence within states and showing the close relationships between interstate and internal violence. In the case of the Democratic Republic of Congo (DRC) for example, this research provides clear, graphic illustration of the fact that a huge proportion of violent conflict in the DRC is part of a trans-border zone of violence in the Great Lakes region. The clear implication is that it cannot be explained primarily in terms of the internal dynamics in the DRC. The lines of territorial control established by local combatants are just as important in understanding patterns of violence in this trans-border zone as the formal international boundaries across which many of them operate. These studies focus on the distribution of violent incidents in space and on correlations between variables at this

Table 1 Theoretical approaches to territory and conflict

Approach	*Method*	*Hypotheses*	*Findings*
Social caging (Michael Mann)	Sociological analysis of long-term historical processes	New economic and coercive structures lead to the 'caging' of the population into dominant power relations	States, organized violence and territorial caging emerge together and are co-constituted
The territorial perspective	Large-n analysis correlating incidence of warfare with interstate territorial disputes	Territorial disputes are more likely to lead to war than other kinds of disputes	Territory is more likely to lead to war because it is a resource and a potent symbol of national identity and its loss effects a nation's reputation
Spatial analysis of conflict	Geographically disaggregated large-n analysis of data on conflict	Local contexts decisively shape patterns of civil war violence	Areas distant from central control and with high population density are at greatest risk of civil war
Micro-level analysis (Kalyvas)	Correlating patterns of violence with levels of territorial control of protagonists	Territorial control decisively shapes patterns of violence	Violence is greatest in zones of disputed control where one group is more powerful, not in zones where their power is more equally balanced
Human territoriality (Sack)	Theorization of power and territory at multiple scales across a broad historical span	Territoriality is a uniquely effective strategy for exerting power	Three primary 'tendencies' in territoriality: enforcement, communication, and classification

disaggregated level. This permits the introduction of new territorially related variables such as distance from capital and from border. But in some senses they are almost as unconcerned with territory as are the state-level studies that preceded them. Despite the fact that they support the argument that state boundaries are not necessarily the boundaries of primary significance in conflicts, the studies tend to treat state borders as a relatively unproblematic variable.

However, other approaches to understanding this kind of local territoriality are possible, and some of the most important advances in understanding territory and conflict have come through rich, localized case-studies. One of the most important early contributions was Charles Tilly's study of counterrevolution in the Vendée in the late eighteenth century (Tilly, 1964). Covering just a few years in one region of France Tilly demonstrated that violence could not be adequately explained in terms of broad national patterns or structural categories such as class. He noted that the revolt was not simply localized to western France but that it was confined to certain subregions in the west and that even within those zones of rebellion, different villages and settlements responded quite differently. Boundaries between local villages and districts could take on intense meanings and importance in times of violent confrontation and territorial bases where sympathizers were densely concentrated were crucial in allowing the counterrevolution to gain momentum.

In 'The Logic of Violence in Civil War,' an analysis of civil war through a case study of violence in one Greek region, Kalyvas (2006) has placed local variation and the territorial unevenness of violence at the center of explanations of civil war, connecting it to distinctions between local and central actors and between the public and the private. He provides a deeply territorial explanation for patterns of violence, focusing not on formal boundaries of any kind, but on the local zones of control established by competing armed actors.

National-level methodologies and explanations have simultaneously been challenged from above, by analyses that emphasize the importance of geopolitical context and external influence in shaping patterns of 'internal' violence. There is a growing recognition across the social sciences that spatial variation, territorial boundaries, and bounding processes are properly located at the heart of any understanding of the causes of war and particularly of civil war. Subnational boundaries in their various forms, whether regional or local boundaries, lines of control established by rebels or no-go areas for state security forces, need to be analyzed in tandem with national borders and need to be understood in the geopolitical context in which all of these territories are ultimately nested (Table 1).

Conflict, Territory, and New Technologies

As new technologies emerge and weaponry develop, society changes; older modes of territoriality are superceded; and the territorial configuration of conflict is transformed. Just as agricultural technologies provided a foundation for the first city-states and the first wars, so the development of powerful artillery in the seventeenth and eighteenth centuries rendered the city walls of medieval Europe redundant. The new-found vulnerability of the walled city contributed in turn to the decline of the city-state as a political formation and the growth of the nation-state. If eighteenth century cannons removed the walls from the city-state, the aerial bombing of the Second World War 'removed the roof' from the nation-state. This new technology rendered the deepest part of the homeland penetrable and vulnerable. In so doing, it blurred the distinction between front line and homeland, and between military and civilian targets. From the siege warfare of the sixteenth century through the set-piece battles of the eighteenth, and the trench warfare of the early twentieth century to the smashing of the distinction between frontline and homeland sanctuary in the Second World War, the territoriality of violent conflict has undergone regular dramatic transformations made possible by new technologies.

The rapid acceleration in the development of new communication and information technologies since the advent

of the World Wide Web in the early 1990s seems to herald another deep historic shift in the territoriality of conflict. The 1990s saw much discussion of 'deterritorialization' and the fading of boundaries. But new technologies facilitated the hardening of boundaries in many cases, as new walls of concrete and wire mesh were put in place across the conflict zones of the Middle East and on crucial borders between first world and third, reinforced with electronic surveillance. Reterritorialization became the preferred catchphrase of the early 2000s as it became clear that shifts in the configuration of territory did not erode the power of territoriality as a strategy for exercising control. The struggle to control territory remained at the heart of violent confrontation.

Pilotless drones now allow technology-rich states to penetrate deeply into the territory of other sovereign states to carry out the kind of precisely targeted attacks that would previously have required a human presence on the ground. Communication technologies allow detailed, direct communication between states and the civilian population of enemy territories. Radio broadcasts into enemy territory during the Second World War were aimed at demoralizing enemy civilians by communicating directly the extent of the detailed local knowledge that the approaching bombers had. The use of mass texting to personal numbers provides a much more focused and effective version of the same phenomenon. The text messages sent in recent years by the Israeli Military to Lebanese and Palestinian civilians informing them that their homes or areas were about to be bombed served the dual aims of reducing civilian casualties and conveying penetration and control of enemy territory. At the same time, online videos, websites, and social networks all provide discussion spaces where civilians associated with opposing parties to conflict can engage in direct communication with the 'enemy.' It is a development that seems unlikely to have a moderating influence on conflict. It seems more likely that direct communication will reinforce and intensify hostility by providing people with direct personal experience of enemy 'aggression' online.

The widening gap in technological capability between protagonists ensures that territory can now be overrun and captured with extraordinary speed by small numbers of troops with superior technology facing a much larger number of opposing forces. The extent of this gap was evident in the lopsided death tolls of recent operations such as the 2003 invasion of Iraq and Israel's Operation Cast Lead in Gaza in 2008/9 – a ratio of a hundred to one in the latter case.

For those holding the new technological cards, territory is easier to penetrate and take, but it is still not easy to hold on to and to dominate in the long term. New technologies, combined with the old-fashioned walls and barriers built around some Iraqi towns and throughout Baghdad, provide crucial tools for maintaining control. Retina-scanning, face-recognition photography, and electronic surveillance combine with physical barriers to permit high levels of monitoring of the general population of certain districts. However,some of the new technologies, such as the mobile phones sometimes used to trigger Improvised Explosive Devices (IEDs) benefit challengers as well as incumbents. Local allies and enforcers remain vital in establishing and maintaining control on the ground. The territorial control that could be exerted at the neighborhood and district level by Shiite militias in Iraq and by groups such as the Northern Alliance in Afghanistan was essential to securing control on the ground – and even then it has proven very difficult to convert swift and overwhelming victory on the battlefield into secure control of conquered territory.

The changing character of territorial conflict in an age of new technologies is a central focus for a great deal of the recent work on space and violence by critical geographers (Elden, 2009; Graham, 2008; Gregory and Pred, 2006). This work is focused to a great extent on recent western military interventions and the geographies of the 'War on Terror.' It deals with issues such as the erosion of territorial sovereignty, the city as battlefield and the geographies of counterinsurgency and examines the imaginative geographies and geopolitical grand visions that shape action on the ground.

Theorizing Territoriality and Conflict

Robert Sack's theory of territoriality is just one of several innovative approaches to power and territory that have emerged since the mid-1980s. It serves here to illustrate the value of new theoretical approaches in advancing our understanding of territorial conflict at a fundamental level. Sack offers an analytical framework that can be applied to boundaries and territories of all kinds and that takes into account the transitory and historically specific character of territorial systems and borders. It also provides a framework for analyzing the role of ideas in the exertion of power through bounding and territoriality.

In his 'Human Territoriality: Its Theory and History' (1986) Sack analyzes territoriality as a uniquely effective strategy for exerting power. He defines it as "the attempts by an individual or group to affect, influence or control people, phenomena, and relationships, by delimiting and asserting control over a geographic area." He describes territoriality as "a primary geographical expression of social power" (1986: 5, 19). These attempts "… to affect, influence or control people" by delimiting and controlling territory are evident first and foremost at the level of the global political system. The apparently natural and eternal division of the planet into sovereign states is maintained to a great extent by the cooperative efforts of nation-states which have a shared interest in elevating the status of existing states as far as possible above the claims of challengers. The value of delimitation as a means of exerting power is evident too at lower levels, in the manipulation of electoral and regional and municipal boundaries to bolster the power of a state or a dominant group or to provide political leverage to a geographically concentrated minority. It is clear too at the lowest scale, in the bounding of neighborhoods deemed to be problematic, in the building of localized barriers that steer movement and interaction and in the creation of special zones of control around key buildings. Nowhere is the power of territory more urgently and dramatically manifested than in situations of violent conflict where the location and strength of boundaries and barriers can make the difference between life and death.

Sack identifies three 'tendencies' that define territoriality. The first of these, enforcement, refers to the way in which control over a multitude of things can be secured by control

over one thing: access. You don't have to enforce a multitude of limitations on behavior in a particular space if you don't let people in to begin with. At the same time you obscure the extent of the control that is being exerted. Communication is the second tendency. The power of boundaries derives partly from their simplicity as a symbol that can nonetheless convey huge volumes of information. Finally Sack identifies classification as a key tendency. Territorial classifications provide a powerful and simple system of ordering that reduces the need to further classify and specify the contents of the delineated space.

Sack's theory is explicitly inter-scalar, theorizing territoriality in such a way that we can analyze the interlinked power of boundaries of different kinds. While Sack focuses primarily on the power exerted through the establishment of formal boundaries, the theory can usefully be applied to all kinds of boundaries.

Although the approach has weaknesses, it nonetheless provides a useful lens through which to view the relationship between territory and power, and between territory and organized violence. It is just one of a number of recent perspectives that can usefully be deployed in pursuit of a deeper understanding of the phenomenon of territorial conflict.

Territorial conflict involves much more than interstate boundary disputes. It involves many different kinds of interrelated boundaries: formal and informal; local, regional, and national; and political and cultural – and it transcends the distinction between internal and external. Indeed, it is the very distinction between inside and out that is at stake in many conflicts: while nationalists and secessionists seek to make the internal external, wars of unification or expansion pursue the goal of internalizing the external. There is accordingly a need for theoretical approaches that can address territorial conflict at these various interlinked levels, that can transcend the distinction between internal and external and avoid privileging the nation-state: an approach that can explain the territoriality of both interstate war and civil wars through the same theoretical lens. Adapting Brighenti's (2010) argument for a new approach to territory and law we might argue that the problem is not to distinguish territorial from nonterritorial conflict or to distinguish the internal from the external but to elaborate "… a concept of territory powerful enough to speak of [organized violence] in its entirety." Brighenti's original quote: "The problem is not separating and opposing territorial and nonterritorial law … rather, elaborating a concept of territory powerful enough to speak of law in its entirety; in other words, to found a territorology of law" (Brighenti, 2010).

Conclusion

There has been a broad shift in recent years from state-based to geographically disaggregated analyses of the causes of violence and from the study of interstate war to the study of civil war violence. This shift has helped to open up several new lines of inquiry in the study of territorial conflict. Theories of territory and power that provide analytical purchase on the relationship between territory and violence, and between territory and legitimacy and order, have much to contribute to the development of these lines of inquiry.

One of those lines of inquiry is the interrelatedness of boundaries of different kinds and at different scales in shaping patterns of violent conflict. Explaining how territories and boundaries are made and maintained in situations of violent conflict requires an approach that treats interstate borders as one more kind of boundary, albeit an exceptionally powerful kind of boundary. Interstate boundaries are related to, lend strength to, and draw strength from many other different kinds of boundaries. If boundaries are crucial in shaping expectations and informing behavior, understanding violent conflict requires a much better developed appreciation of the connections between violence and the making of territory.

There also remains much scope for work on the way in which the global state system shapes the forms that territorial disputes take, work that might help to explain why we have seen such a marked shift in recent decades from interstate war to civil war. A rigid global system in which there are immense pressures against the modification of interstate boundaries may well help to push territorial struggles down to lower levels, displacing them rather than eliminating them. In Bosnia and Herzegovina and in the Kurdish region of Northern Iraq, to take two of the clearest examples, strong internal borders confer almost as much autonomy and power on regionally concentrated minorities as international borders without presenting a direct challenge to the interstate system. In the case of Iraq, the struggle over the exact location of the internal boundary and over the control of local spaces, has taken on much of the character of an interstate boundary dispute. Here we have a clear example of a boundary dispute that could easily be converted into a secessionist and ultimately an interstate dispute, but for a political calculus in which the global state system weighs heavily.

Finally, we have the question of how new information and communication technologies are reshaping the territorial configuration of violent confrontation. Are the new technologies facilitating deep shifts in the processes by which borders and territories of all kinds are maintained and reproduced? How do new technologies of bounding and penetration impact on the territorial dynamics of violent conflict? If communication is a central dimension of territoriality, how do new forms of communication effect the deployment of territorial strategies? The work in this area is still in its infancy. It stands out as perhaps the most important and urgent topic in the understanding of contemporary territorial conflict.

Abstract

Human geographers situate territoriality in a social and political context in which territories are seen to be socially produced and territorial strategies can be seen as mechanisms to achieve particular ends. The control of geographic space can be used to assert or to maintain power, or to resist the power of a dominant group. Rather than being natural entities, territories reflect specific ways of thinking about geographic space and they emerge from social practices and processes that link space and society. These geographic spaces convey messages of political power and control which are communicated through various means and the creation, maintenance, and patrolling of boundaries divides those inside from those outside. Control over territory is a key political motivating force and territoriality can be seen as a spatial manifestation of power. While some of the most obvious territorial constructions and visible expressions of territoriality occur at the level of the state, many more micro-scale examples may be observed. Territorial strategies can be used in order to express an identity while territorially transgressive acts can be employed to reclaim space and, hence, to assert basic rights.

Most people are regularly confronted with signs warning 'authorized personnel only,' 'no trespassing,' 'prohibido el paso,' and so on. Such regular warnings and admonishments are a reflection of attempts to impose forms of power (via sets of rules and regulations) through control of portions of geographic space. Space is claimed, boundaries are produced and patrolled, and territorial strategies are deployed across a range of spatial scales. Such strategies are not always successful and claims on space are often contested and boundaries transgressed. The various manifestations of human territoriality might lead to an assumption that it is an innate biological urge. While it is tempting to relate territorial behavior to some inbuilt feature of human beings, more nuanced perspectives suggest that much of our territorial behavior is a consequence of our broader sociopolitical conditioning. By and large human geographers tend to locate human territoriality in its social and political (rather than biological or genetic) context.

Whether explicit or implicit, control over territory is a key political motivating force and territorial practices are linked to the interplay of social and political forces. Territoriality can be seen as a spatial expression of power and the processes of control and contestation over portions of geographic space are among the central concerns of political geography (Storey, 2012). Any consideration of territories necessarily raises questions to do with boundaries. The borders of a territory may be quite clearly defined and formalized, as between most countries, or they may be somewhat informal or ill-defined, as is the case when considering the territories of rival urban gangs whose 'patch' or 'turf' may well have a core but the precise boundaries of which may be unclear. The demarcation of territories and the bounding of space obviously bring with them issues of exclusion and control and territories, and their boundaries, are often the center of disputes (in many instances quite violent) and the areal extent of particular territories (and even their right to exist) may be regularly called into question. Rather than being fixed immutable entities, human territories and their boundaries are subject to periodic or continuous contestation, modification, transformation, and destruction (Paasi, 2008). The global political map provides visible illustration of the most obvious manifestation of the territorial dimension to politics in the division of the earth into separate countries or states, but territories are also produced, controlled, bordered, and contested across a range of spatial scales and in a wide range of contexts. The following discussion explores territory and territoriality from a geographic perspective, it examines the concept of territory, and it explores the links between territorial formations and behavior, and senses of identity and belonging.

Territoriality

Crude deterministic perspectives suggest a territorial imperative that is seen as a natural and unchanging phenomenon. This viewpoint holds that the need for space is a characteristic innate to all species, including humans, and there is an associated impulse to defend this territory against others seeking to 'invade' it (Ardrey, 1967). Parallels between the behavior of humans and animals were popularized by the zoologist, writer, and broadcaster Desmond Morris (1994), among others, who characterized humans as basically territorial creatures with an innate need to defend territory, whether at the level of the nation or at the micro-scale level of the home. These sorts of analogies with animal behavior have a long history. The geographer Friedrich Ratzel developed organic theories of state formation in the late nineteenth century suggesting state expansion was a necessary means of ensuring a country's survival. Drawing parallels with evolutionary theory he suggested that states needed to adopt 'survival of the fittest' strategies in order to retain power, an argument serving as a convenient justification for aggressive territorial defense and acquisition (Bassin, 1987). These sorts of determinist argument attribute many human characteristics to nature and employ ideas from the natural sciences in attempting to explain human behavior. This is then seen as innate rather than emerging out of our social and cultural conditioning. However, while there may well be behavioral

parallels between animals and humans, it does not follow that the motivating factors are the same.

Contemporary geographical contributions to the study of human territoriality have tended to align with wider arguments within the social sciences which suggest human behavior is heavily conditioned by the economic, social, political, and cultural environment in which we exist. Central to this perspective is an emphasis on power relationships rather than biology or genetic inheritance. Soja (1971) suggests that, although characteristics such as aggression and territoriality are displayed by humans, this does not mean that there is anything inevitable about them or that they cannot be altered or avoided. Rather than adopting simplistic deterministic explanations, or getting entangled in the intricacies of nature–nurture debates, it seems reasonable to assume we are subject to complex sets of influences within our broader environment and these influences interact with our genetic potential.

Two geographers who have contributed significantly to debates on human territoriality are Jean Gottmann and Robert Sack. Gottmann argues that territory, and the assertion of control over it, represents an expression of power. In his view, territory confers security through the control of defensible space while also providing opportunities through facilitating the economic organization of that space. This emphasis on security and opportunity points to a political and economic basis for territorial formations which make for a more efficient means of political organization than systems of overlapping jurisdictions. Sack emphasizes the role of territoriality as a geographic and political strategy through which individuals or groups endeavor to "affect, influence, or control people, phenomena, and relationships, by delimiting and asserting control over a geographic area" (1986: 19). He emphasizes the instrumental nature of territoriality and draws attention to the means through which territorial strategies may be used to achieve particular ends so that control of geographic space can be used to assert or to maintain power, or, importantly, to resist the power of a dominant group. What this means is that territoriality is deeply embedded in social relations so that territories, far from being natural entities, are the result of social practices and processes and are produced under particular conditions in order to serve specific ends (Delaney, 2005).

These perspectives are important in not only emphasizing the political context of territorial behavior but also in highlighting how territoriality as a strategy operates at all spatial scales from the geopolitical strategies of global superpowers down to the home and the workplace. Sack also draws attention to the significance of territoriality in facilitating classification, communication, and enforcement. Territoriality involves a classification by geographic area through which space is seen to be apportioned between states or between individuals. In this way, a room, or an office workstation becomes 'my' territory and others are only permitted to be there as 'guests.' Sack also argues that territoriality is easy to communicate via the use of boundaries which indicate territorial control and, hence, power over prescribed space (and of those within it). In this way, there is a distinct separation between those who are 'inside' and those who are 'outside,' thereby conveying clear messages about power and control. In this way, territory and border construction in classifying space and communicating power act as devices for the enforcement of authority. This may have important implications such as constraining, restricting, or limiting people's mobility, for example. Territories and territorial ways of thinking link space and society and serve to convey clear meanings relating to authority, power, and rights (Delaney, 2009).

Another tendency of territoriality identified by Sack is that it functions as a means through which power is reified. Through the visibility of land (or a room or a desk) power can be 'seen' in a way which suggests "territory appears as the agent doing the controlling" (Sack, 1986: 33). This reification is most obviously apparent in the deployment of the term 'the law of the land' whereby power appears to reside in the territory itself rather than in those who control. Attention is thereby diverted away from the power relationships, ideologies, and processes underpinning the maintenance of territories and their boundaries. In this way, "territory does much of our thinking for us and closes off or obscures questions of power and meaning, ideology and legitimacy, authority and obligation" (Delaney, 2005: 18). This interpretation of territorial behavior emphasizes the political functions of territoriality so that it can be seen as "a primary geographic expression of social power" (Sack, 1986: 5).

The Emergence of Territory

While Sack's functionalist emphasis is clearly important, a somewhat less instrumentalist view emerges in the work of the Swiss geographer Claude Raffestin (2012). He views territoriality in a somewhat broader way, seeing it as a process produced by the various relationships between individuals and groups and their wider social environment, not just something bound up with the attainment of particular goals. Raffestin's concern is with the emergence of territories out of social interaction, not solely with the operation of territorial strategies. In a connected vein, Stuart Elden has drawn attention to the concept of territory itself. He argues that within debates on territoriality, the idea of territory has been taken for granted so that "strategies and processes toward territory…conceptually presuppose the object that they practically produce" (2010). He suggests that territories themselves, and their boundaries, reflect a distinctive mode of social and spatial organization which is linked to particular ways of thinking about geographic space and these ways reflect notions of power and control. Elden argues that our contemporary ideas of territory emerged as a consequence of developments in cartography and spatial calculation; it is something that can be calculated, mapped, and controlled. The features of territoriality identified by Sack (1986), in allowing classification and differentiation, are thus products of the ways in which space is imagined and territories are in effect politicized space; mapped and claimed, ordered and bordered, measured and demarcated (Elden, 2007).

If territories reflect a particular way of thinking about space, then this points to the importance of maps in solidifying and legitimizing these spatial units. Rather than neutral depictions of supposed geographical realities, a more critical analysis suggests that maps have always been useful weapons in larger political projects associated with territorial claims and counterclaims (Wood, 1992). Mapping of territory itself functions so as to enhance power sending out messages signifying control

over portions of geographic space. Maps of the British Empire conventionally depicted Britain's overseas territorial possessions in pink which not only conveyed (often limited) information but more importantly broadcast a clear political message of power over roughly one quarter of the planet's land area. Advances in cartography and spatial calculation modified the ways in which space was considered and emerged alongside attempts to apportion and control it. The military and political underpinnings of cartographic developments should not be ignored and the consequent role of mapping (in both practical and symbolic terms) in the creation of colonial territory was a key element in the imposition and maintenance of political control.

The Territorial State

The creation of states and the construction of borders between them represent the most obvious political expression of territoriality and much geographical coverage of territory and territoriality focuses on these. The Westphalian state has become the world's dominant mode of political organization and it is difficult to conceive of a world without states and borders, so firmly embedded has it become. Territory is the functional space within which the state operates and wields power and can be seen as a key and necessary feature of the state. Borders are the dividing lines where state control both begins and ends. While the territorial state is at the center of the global political system, we need to be careful not to fall into what Agnew (1994) terms the territorial trap whereby we naturalize states and their borders. He argues that states are imagined as fixed sovereign entities with power over their territory, in turn suggesting a clear distinction between 'domestic' and 'foreign,' whereby states are characterized as territorial containers of economy and society. However, Brenner and Elden (2009) (drawing on the work of Henri Lefebvre) point to the ways in which territory is continually reproduced through the actions of states and through various forms of political struggle. They argue that territory, rather than simply being a feature of the state, both facilitates and emerges from state action. Clearly sovereignty and the state system place a heavy emphasis on geographical borders that separate one territorial political entity from another. Borders are often seen as taken for granted features serving as political–cultural dividing lines. However, they might more accurately be seen as discursive constructs that serve to legitimize the state (Fall, 2010; Newman, 2010). Not surprisingly, boundary disputes often lie at the heart of many conflicts and such disputes regularly emerge in regions with considerable ethnic complexity.

Territory and borders are necessary features of the contemporary state but these are closely linked to ideas of sovereignty or the right of the state to control its people and its territory. Agnew (2005) argues that sovereignty is highly complex and the sovereign power of an individual state is continually challenged, contested, and modified. Processes associated with globalization (or linked together under that broad umbrella term) are seen by many as signaling a diminishing sovereignty for the territorial state. Borders are commonly depicted as increasingly porous in a world of transnational flows of people, goods, finance, and ideas. The emergence of regional economic alliances, epitomized by the evolution of blocs such as the European Union and the Association of South East Asian Nations, is heralded by some as the successor to the state system in an increasingly globalized world where state boundaries are assumed to have diminishing significance. The spatial diffusion of the financial crisis in recent years points to a diminishing ability of the state to maintain economic sovereignty. However, predictions of the demise of the state and the advent of a borderless world seem somewhat exaggerated. While a neoliberal economic orthodoxy (and its attendant crises) centered on trans-global economic flows seems to point toward the irrelevancy of borders, it simultaneously utilizes and reconfigures them in attempts to increase the returns to capital. In addition, there is the apparent paradox that while capital flows relatively freely across international frontiers, many people (depending on who they are, where they are from, and where they are trying to go) are faced with the intimidating paraphernalia of the state manifested at border crossing points.

Geopolitically, Elden (2010) and others suggest that, far from disappearing, territory is continually being reconfigured and spatial political relations are constantly being reshaped in ways suggestive of reterritorialization rather than deterritorialization. Power is unequally distributed and some political–territorial formations exert significantly more than others. The US detention center of Guantánamo Bay provides one example of the increasingly complex nature of territorial sovereignty with the highly strategic use of a geographically bounded space that is both simultaneously under US control while also outwith the ordinary political jurisdiction of the country (Reid-Henry, 2007). Sovereignty, for some, is contingent on adhering to particular ground rules laid out by the more powerful. External interventions by Western powers in a range of regions (including Iraq, Afghanistan, Libya, Syria, Mali) serve to demonstrate that territorial sovereignty is highly contingent on the behavior of a state with major powers appearing to reserve the right to intervention. While such actions are often clothed in the language of civil rights and humanitarianism, in reality they are usually bound up with the advancement of the strategic interests (economic and political) of powerful elites. Some states display a willingness and ability to exert power well beyond their formal territorial boundaries while others (sometimes labeled 'failed' or 'rogue' states) become arenas for external intervention. The linkages between state sovereignty and territorial control are far from straightforward and lead to a consideration of effective sovereignty wielded by both states and quasi-state actors and deployed across a range of territorial contexts (Elden, 2009; McConnell, 2010).

Of course these contemporary geopolitical strategies are nothing new. Empire-building by European powers represented a territorial expression of power on the part of those countries which led to much of the world's surface area being carved up between them and out of which there has been an enduring territorial legacy (together with a range of economic, political, and cultural consequences) throughout Africa, Asia, and the Americas. More recently, the Cold War era of the middle years of the twentieth century saw the United States and the Soviet Union seeking to establish geographical spheres of influence. While this might not have been formalized territorial

control, it was a process whereby 'friendly' governments were encouraged, or sometimes forcibly installed, in countries which the superpowers saw as vital to their strategic interests. Some would argue that the ongoing creation and maintenance of military bases in other countries and the economic and political pressures exerted (both directly and indirectly) by major powers further highlights the contingent nature of state sovereignty while reflecting a contemporary version of colonialism through which subject peoples and territories are maintained in a subordinate position (Harvey, 2003; Gregory, 2004).

Territory, Place, and Nation

While drawing attention to the emergence and functions of territories, it is important to note that the phenomenon should not be reduced to a mere commodity or territories seen simply as (sometimes leaky) spatial containers. Territories, and the ways in which they are imagined, can play an important role in the formation of peoples' self-identity and contribute to feelings of belonging or exclusion. The intrinsic geographic importance of territory is stressed by Soja who suggests it "provides an essential link between society and the space it occupies primarily through its impact on human interaction and the development of group spatial identities" (1971: 33). Once created, territories can become the spatial containers in which people are socialized through various social practices and discourses. Paasi (2008) suggests that a number of important dimensions of social life and social power are brought together in territory. These include a material component such as land, a functional element reflected in control of (or attempts to control) space and a symbolic component associated with people's social identity. The social, cultural, and political are brought together so that people identify with territories in such a way that they can be seen "to satisfy both the material requirements of life and the emotional requirements of belonging" (Penrose, 2002: 282). Although Sack (1986) suggests that territoriality forms a backcloth to human spatial relations and conceptions of space, territory is much more than this, and more also than simply the material manifestation of sets of social relations. As Sack himself also intimated territory is a device through which we experience the world and give it meaning. The spatial is not simply the outcome of the social but the two are intrinsically interwoven so that territories, and territorial strategies associated with them, can be seen as powerful influences shaping social life (Delaney, 2009).

This is very evident in the context of national space where there is a significance seen to be attached to a national territory, reflected in territorial claims and various expressions of ethnonational identity and belonging. Nations (as distinct from states) can be seen as groups of people linked through a sense of a common identity bound together by feelings of a shared history and an attachment to an identifiable territory or homeland. While nations might be seen as comparatively 'modern' constructions they rely heavily on history, myth, and territory. Nationalism is both a political and territorial ideology in which a 'national' territory is defended, claimed, or sought in the name of the 'nation,' though the construction of nationhood is almost always a highly contested process in which competing narratives are pitted against each other. Territory is quite central in many nationalist discourses and is habitually invoked in national conflicts where both generic territory and specific places may acquire enormous symbolism. References to the national soil abound so that fighting for, or even dying for, the land are often seen as supreme acts of patriotism in times of national conflict. A second element in the connections between land and identity is the 'production' and veneration of generic landscapes. Particular parts of the national territory may acquire a significance as the presumed heartland or 'core' of the nation. Nationalist conflicts periodically give rise to attempts to create ethnically pure spaces linked to the mythologizing of certain places and associated boundary-making, as apparent in the Balkan disputes of the 1990s (Kolstø, 2005). Mobilization around ethnic identities provides one example of the forces that may give rise to pressures for territorially based entities to secede and to create new states.

Territory, Space, and Society

While some of the most obvious (and contested) expressions of territoriality are manifested at the level of the state, many more micro-level examples of territorial control and territorial strategies may be observed and this is reflected in the creation and sustaining of a vast array of spatial enclaves (Sidaway, 2007). Social practices associated with race, class, gender, and sexuality are spatialized with boundaries constructed and contested in people's everyday lives while territorial strategies are used to control and to resist (Storey, 2012). Issues of identity frequently have a spatial expression as social fractures are given material form through spatial divisions. While these spaces might not necessarily be regarded as territories (and may be less obvious, more vaguely defined, and with less clear-cut boundaries) these more micro-scale contexts provide insights into the ways in which geographic space is politicized through attempts to achieve particular outcomes, to exert (or resist) control, and to convey quite clear meanings to those concerned (Delaney, 2005). One manifestation is through the geographies of residential housing. Class divisions are reflected in patterns of residential segregation and processes of gentrification so that poorer or working-class neighborhoods are distinguished from middle-class or more affluent areas. The emergence of gated communities is perhaps the most obvious and clearly demarcated manifestation of this wider and long-standing phenomenon (Le Goix and Webster, 2008). In some contexts, this is accompanied by clustering (or separation) along ethnic lines with the emergence of ghettos and other areas with high concentrations of specific ethnic groups. Discriminatory ideologies and class divisions, often reinforced through planning policies, may contribute toward the exclusion of people from particular areas and the negative stereotyping of such places and their residents. In these areas, segments of the population, often the young, may feel particularly marginalized and one manifestation of such problems of exclusion, marginalization, and victimization may be outbreaks of civil unrest, as in many French cities in recent years (Dikeç, 2007). Some urban areas are sites of territorially based gang behavior (often at the level of the

street or postcode demarcation), a phenomenon that itself feeds into further cycles of stigmatization of places and those who live there (Ralphs et al., 2009).

Alongside residential segregation, recreational spaces such as golf courses, wider tourist complexes, or beach resorts in various parts of the world can be seen as further examples of spatial enclaving designed to enclose the relatively privileged consumers from the excluded local 'other' (Bunnell et al., 2006). These increasingly privatized spaces of consumption have developed in tandem with other controlled arenas such as shopping malls which reflect an erosion of shared public space and its replacement with privatized, exclusionary, and highly regulated environments (Staeheli and Mitchell, 2006). Alongside the creation of various other economically driven territorializations such as export processing zones, a wide array of spaces of exclusion continue to emerge which might be viewed as the outcome of an inherent tendency within capitalist social relations leading toward the ever-increasing privatization of the public domain (Vasudevan et al., 2008).

Feminist perspectives in geography have drawn attention to the nature, construction, and legitimacy of a public–private divide. The 'naturalizing' of specific roles has had a spatial corollary. Long-standing stereotypes of women as home makers whose rightful place is in the domestic realm have given rise to a gendering of space and the use of a territorial frame to restrict women's access to a wider public domain. Such divisions are reinforced through various geographies of fear so that women may be afraid to walk through some areas or frequent specific streets due to fear of assault. These gendered constructions also prompt broader questions about the nature and meanings attaching to 'home' and the social construction of domestic space (Blunt and Dowling, 2006). Similar issues may impact on sexual minorities who may lead more spatially restricted lives due to fear of physical or verbal homophobic abuse. At a yet more micro-level, territorial behavior occurs in all sorts of different settings including the workplace, the office, or the school playground (Thomson, 2005). For example, the demarcation of particular rooms within a house is also a form of territorial behavior through which power (to include or to exclude) is expressed. Parental power is often expressed territorially through, for example, discouraging children entering some rooms in the house such as the kitchen or the parents' bedroom. Similarly, the prohibition of employees from certain rooms or areas within their place of work is an assertion of managerial power. These territorially based constructions of difference can have profound social and spatial impacts raising important questions about power, dominance, and control.

While territorial constructions and strategies are used to impose forms of control they are also resisted. From the activities of revolutionary groups such as the Zapatistas in Chiapas in Mexico to 'reclaim the night' marches, constant struggles are engaged in as attempts are made to control space or to wrest space from other groups. Resistance may be enabled and solidified through senses of place identity which help facilitate forms of action aimed at obtaining particular outcomes. The formation of community or residence groups may reflect feelings of belonging or attachment to a particular place and this territorial affinity may play a mobilizing role. Territorially transgressive acts, whether protest marches or the painting of graffiti, can be employed to reclaim space and to assert basic rights and identities. Responses to homophobia may be reflected spatially through the emergence of spaces where gay people may feel more at ease through being accepted rather than rejected, scorned, or ignored (or worse) by their neighbors (Browne et al., 2007). Just as dominant ideologies can be reinforced through territorial practices, they can also be resisted. Territorial strategies are useful mechanisms in the assertion of identity and spatial concentrations within particular geographic areas make visible people and issues that might otherwise remain unseen. They can be used to draw attention to exclusionary practices and to assert the right to be equal citizens.

Summary

Territories are political geographic entities that have emerged out of particular ways of conceiving geographic space. Territory often constitutes a major component in shaping our everyday lives and in contributing to our senses of place, identity, and belonging. Particular ideologies and social practices are manifested spatially and are reflected in struggles and territorial claims over the use and control of space. Territorial strategies are utilized in conflicts concerned with social power and identity at a range of spatial scales from the global down to the very local. These strategies may be to do with maintaining power or with resisting the imposition of power by a dominant group. Exclusionary ideologies may be consolidated and reinforced through territorial practices, yet they can also be resisted through similar means. The desire to exert territorial control needs to be viewed in its broader social and political context, and not seen simply as a response to an elementary biological urge. Territoriality is a mechanism of power and territorial formation, control, resistance, and transgression are all political phenomena. While it might be supposed that places and territorial boundaries are becoming less and less significant in an increasingly globalized world, the (re)production of territories and the associated creation and contestation of boundaries seem likely to continue to be important for the foreseeable future.

Terror and the Internet

Gabriel Weimann, University of Haifa, Haifa, Israel

Abstract

Paradoxically, the most innovative network of communication developed by modern Western societies – the Internet with its numerous online networking platforms – now serves the interests of the greatest foe of the West, namely, international terrorism. The growing presence of modern terrorism on the Internet is at the nexus of two key trends: (1) the democratization of communications driven by user-generated content on the Internet and (2) the growing awareness of modern terrorists of the potential of the Internet for their purposes. The Internet has long been a favorite tool of the terrorists. Decentralized and providing almost perfect anonymity, it cannot be subjected to control or restriction, and allows access to anyone who wants it. Large or small, terrorist groups have their own Web sites, using this medium to spread propaganda, raise funds, seduce, radicalize, recruit and train members, communicate and conspire, and plan and launch attacks. Besides thousands of terrorist Web sites, modern terrorists rely on chat rooms, e-groups, forums, social networking, and online platforms like YouTube, Facebook, Twitter, and more. Thus, media-oriented terrorism has presented a tough challenge to democratic societies and their liberal values.

Mass-Mediated Terrorism

> When one says 'terrorism' in a democratic society, one also says 'media.' For terrorism by its very nature is a psychological weapon which depends upon communicating a threat to a wider society. This, in essence, is why terrorism and the media enjoy a symbiotic relationship.
>
> (Wilkinson, 2001: p. 17)

From its early days, terror has combined communicative and psychological aspects. Specifically, the word 'terror' comes from the Latin word 'terrere,' which means 'to frighten' or 'to scare.' The first use of large-scale terrorism was in fact state terrorism, emerging during the popular phase of the French Revolution. The period from June 1793 to July 1794 in France is known as the Reign of Terror or simply 'the Terror.' The upheaval following the overthrow of the monarchy threw the nation into chaos and the government into frenzied paranoia. The Revolutionary Tribunal sentenced thousands to the guillotine. Nobility and commoners, intellectuals, and politicians and prostitutes, all were marched to 'Madame Guillotine' or 'The National Razor.' Estimates of the death toll is placed between 16 000 and 40 000. The executions were conducted before large audiences and were accompanied by sensational publicity thus spreading the intended fear.

Modern terrorists have become exposed to new opportunities for exerting mass psychological impacts as a result of technological advances in communication technologies. They replaced the public executions in Parisian squares with spectacular violent productions performed on the global stages of the mass media. Government officials have tended to blame the media with terrorists' success, as the then British Prime Minister Margaret Thatcher argued: "democracies must find ways to starve the terrorists and hijackers of the oxygen of publicity on which they depend" (as cited by Picard, 1991: p. 50). More recently, Kratcoski has wryly commented that "if one of the elements of terrorism is the wish to obtain publicity for a cause and create propaganda, the media has obviously overreacted in responding to this desire" (Kratcoski, 2001: p. 468).

The emergence of media-oriented terrorism led several communication and terrorism scholars to reconceptualize modern terrorism within the framework of symbolic communication theory. As Jenkins concluded in his analysis of international terrorism, "Terrorist attacks are often carefully choreographed to attract the attention of the electronic media [radio, television] and the international press. Taking and holding hostages increases the drama. The hostages themselves often mean nothing to the terrorists. Terrorism is aimed at the people watching, not at the actual victims. Terrorism is a theater" (Jenkins, 1975: p. 4). Weimann adopted the 'Theater of Terror' metaphor to examine modern terrorism as an attempt to communicate messages through the use of orchestrated violence (Weimann, 1983, 1987, 1988, 1990, 2004, 2008; Weimann and Winn, 1994).

Modern terrorism can be understood in terms of the production requirements of theatrical engagements. Terrorists pay attention to script preparation, cast selection, sets, props, role playing, and minute-by-minute stage management. Just like stage plays or ballet performances, the media orientation in terrorism requires full attention to detail to be effective. One of the most influential strategist of modern terrorism was the Brazilian Carlos Marighela, whose *Minimanual of the Urban Guerrilla* became a sourcebook for many terrorist movements all over the world. In his publications, Marighela (1971a,b) outlined the various uses that can be made of the media:

> The coordination of urban guerrilla action, including each armed action, is the principal way of making propaganda. These actions, carried out with specific and determined objectives, inevitably become propaganda material for the mass communication system. Bank assaults, ambushes, desertion and diverting of arms, the rescue of prisoners, executions, kidnapping, sabotage, terrorism, and the war of nerves, are all cases in point. Airplanes diverted in flight, ships and trains assaulted and seized by guerrillas, can also be solely for propaganda effects.
>
> (1971b: p. 103)

The most powerful and violent performance of modern terrorism was the 11 September 2001, attack on American targets. In November 2001, shortly after the 9/11 attacks, Osama bin Laden discussed the twin attacks. Referring to the kamikaze pilots whom he called 'vanguards of Islam,' bin Laden marveled, "Those young men said in deeds, in New York and Washington, speeches that overshadowed other speeches made everywhere else in the world. The speeches are understood by both Arabs and non-Arabs, even Chinese."(Quote from the translated transcript of a videotape; cit. B. Nacos (2003b: p. 41).) With these remarks, argues Nacos (2003a), bin Laden revealed that he considered terrorism first and foremost as a vehicle to dispatch messages – 'speeches' in his words – and, with respect to the events of 11 September 2001, he concluded that Americans in particular had heard and reacted to the intended communication.

When New Terrorism Met the New Media

The emergence of media-oriented terrorism and its growing sophistication in manipulating the media have led governments and media organizations to react by regulating terrorists' access to the conventional mass media, reducing and censoring news coverage of terrorist acts and their perpetrators, and minimizing the terrorists' capacity for manipulating the media. However, the new media technologies, especially computer-mediated communication and the Internet, allow terrorist organizations to send messages more freely and easily than through other means of communication. al-Qaeda, for example, is using online platforms and advanced communication technologies in a most sophisticated way (Weimann, 2004, 2006). In his assessment of al-Qaeda, Hoffman (2003: p. 4) noted this "long-established sophistication of bin Laden and al-Qaeda's propaganda efforts – employing multimedia vehicles, including prerecorded video and audiotapes, CD-ROMs, DVDs, and the Internet; dramatically choreographed and staged dissemination opportunities; and other mass outreach techniques (e.g., via al Qaeda's phantom Alneda website and those of sympathetic, above-ground radical Islamic sites and organizations)." With the Internet, terrorists can bypass the regulations, limitations, and censorship imposed by traditional media and directly reach hundreds of millions of people, globally.

Terrorist organizations have generated thousands of Web sites that support psychological warfare, propaganda, fund raising, recruitment, coordination, and inner communication. From these terrorist sites, supporters and followers can download multimedia training materials; buy games, T-shirts, and music CDs; and access forums, social networking sites (such as Facebook), and chat services (Weimann, 2006). Most of these sites are extremely dynamic in that they emerge overnight, frequently modify their contents, and then swiftly 'disappear' by changing their URLs, which are later announced via online forums (Weimann, 2006). They are often hosted on free space providers or by unsecured and poorly maintained commercial servers. The level of technical sophistication of the terrorist Web sites has increased dramatically in recent years.

The great virtues of the Internet – ease of access, lack of regulation, vast potential audiences, fast flow of information, and the availability of multimedia platforms – have been converted into the advantage of groups committed to terrorizing societies to achieve their goals. The anonymity offered by the Internet is very attractive for modern terrorists (Rogers, 2003): due to their extremist beliefs and values, terrorists require anonymity to exist and operate in social environments that may not agree with their particular ideology or activities. The Internet provides this anonymity as well as easy access from everywhere with the option to post messages, e-mail, upload or download information – and to disappear into the dark.

Terrorist Web Sites and Forums

It is easy for terrorists to set up a Web site. Take for example, the al-Qaeda's original Web site, alneda.com. In the case of alneda.com, al-Qaeda members created a fictitious organization, 'The Center for Islamic Studies and Research,' a bogus street address in Venezuela, and a free Hotmail e-mail account to contact Emerge Systems, a Web hosting company in Malaysia, US intelligence officials say. The group then wired $87 to a Malaysian bank to pay for the cost of the Web site for a year. Just before alneda.com was pulled off its server (in July 2002), it warned its members that the Federal Bureau of Investigation (FBI), Central Intelligence Agency, and Customs Service were probably monitoring the site. It promised to e-mail members the new address of the site once it was in operation. It also told them they could find the address in chat rooms on other terror sites, such as Hamas' qassam.net. Within years, al-Qaeda launched (either directly or indirectly) thousands of Web sites, forums, chat rooms, and so on. These Web sites are used to disseminate lectures, announcements, videos of terrorist activities, guidebooks, and instruction manuals.

The rise of networked terrorist groups is part of a broader shift to what Arquilla and Ronfeldt (2001a,b) called 'Netwar.' Netwar refers to an emerging mode of conflict and crime at societal levels, involving measures short of traditional war in which the protagonists are likely to consist of small, dispersed groups who communicate, coordinate, and conduct their campaigns in an 'internetted' manner and without a precise central command. Netwar differs from modes of conflict in which the actors prefer formal stand-alone hierarchical organizations, doctrines, and strategies, for example, as in past efforts to build centralized revolutionary movements along Marxist lines. Netwar can be launched by various actors, ranging from NGOs and social activists to violent terrorists.

Terrorist Online Networking

In addition to launching their own Web sites, terrorists can harness the interactive capabilities of the Internet using chat rooms, instant messengers, blogs, video-sharing Web sites, and thousands of postings on Facebook, MySpace, Twitter, and YouTube (Kennedy and Weimann, 2011; Weimann, 2011). As Kohlmann concluded his monitoring of online terrorist presence: "Today, 90% of terrorist activity on the Internet takes place using social networking tools, be it independent bulletin boards, Paltalk, or Yahoo! eGroups. These forums act as a virtual firewall

to help safeguard the identities of those who participate, and they offer subscribers a chance to make direct contact with terrorist representatives, to ask questions, and even to contribute and help out the cyberjihad" (Kohlmann, as cited by Noguchi, 2006; web page).

Online social networking is another mean of attracting potential members and followers. These types of virtual communities are growing increasingly popular all over the world, especially among younger demographics. Youths are especially targeted for propaganda, incitement, and recruitment purposes by jihadist terrorist groups. Predominately Western online communities like Facebook, MySpace, and Second Life and their Arabic equivalents are being used more and more by terrorist groups and their sympathizers.

Social networking Web sites allow terrorists to disseminate propaganda to an impressionable age bracket that might empathize with their cause and possibly agree to join. Many users join interest groups that may help terrorists target users whom they might be able to manipulate. Many social network users accept people as friends whether or not they know them, thereby giving perfect strangers access to personal information and photos. Some people even communicate with the strangers and establish virtual friendships. Terrorists apply the narrow-casting strategy to social networking sites as well. The name, accompanying default image, and information on a group message board are all tailored to fit the profile of a particular social group. The groups also provide terrorists with a list of predisposed recruits or sympathizers. In the same way that marketing groups can view a member's information to decide which products to target to your Web page, terrorist groups can view people's profiles to decide whom they are going to target and how they should configure the message.

As a strategy to distribute jihadist propaganda to a wide range of Muslims and overcome countermeasures, a jihadist posting suggests that administrators of jihadist forums and media organizations create e-mailing groups. This suggestion was posted on the al-Fallujah jihadist forum on 16 March 2009. The mailing group is patterned after the Ansar Mailing Group, an inactive jihadist media distributor that dispatched news of the mujahedeen to users via e-mail. He suggests that other jihadists, too, create such groups to reach the largest possible number of users and that they should remove any obstacle in the registration process that hinders distribution. To this end, the jihadist, in a later posting, provides instructions for creating groups on Google. Another forum participant, pleased with the suggestion, instructs how to create a user account on Yahoo and adds that groups may be created on that service.

A recent report by the Student Rights and the Henry Jackson Society shows that British students are being targeted online by Islamist extremists using social media (Sutton and Stuart, 2012). The study reveals how online platforms are used to promote fear of a Western war against Islam, support for paramilitary violence in Israel, intolerance of nonbelievers and Islam as an obligatory political system for law and governance. Chilling videos of armed insurgents, accompanied by hate-filled speeches from leading al-Qaeda figures, have been posted on Web sites linked to Islamic societies at several leading British universities. The social media were used to share extremist material including video and audio recordings of Abu Ibrahim, designated by the US government as an al-Qaeda linked fighter, recruiter, facilitator, and propagandist; Abdul Rahman Saleem, convicted in 2008 of inciting terrorism overseas during a speech at Regent's Park mosque; and of deceased senior al-Qaeda cleric and propagandist Anwar al-Awlaki.

Terrorist Chat Rooms

Chat rooms and electronic forums enable terrorist groups to communicate with members and supporters all over the world, to recruit new followers, and to share information at little risk of identification by authorities. The free chat room service PalTalk, which includes voice and video capabilities, has become particularly popular with terrorist cells. In one PalTalk chat room, British Islamic militants were found to have set up support forums for the killed leader of the insurgents in Iraq, Abu Musab al-Zarqawi. In one chat room, Arabic-speaking users are sharing personal experiences of fighting Arab-Afghans. In another, relatives of Iraqi insurgents were praising the 'martyrdom' of the terrorists (Kohlmann, 2005). On the alneda.com forum, al-Qaeda members posted comments praising Osama bin Laden, such as "Oh Allah! support your fighting slave Osama bin Laden." Other message boards included threats against global security and reference to the 2005 London bombings. The Web site and forum were hacked into and closed down. But that did not stop al-Qaeda members. They simply started a new forum.

In addition to being used to generate support, chat rooms are used to share tactical information. Jihadist message boards and chat rooms have been known to have 'experts' directly answer questions about how to mix poisons for chemical attacks, how to ambush soldiers, how to carry out suicide attacks, and how to hack into computer systems. One chat room on the PalTalk index, with a name that is slightly altered each time but still identifiable, has been routinely advertised on Jihadi web forums and has been used on a daily basis to post the links for al-Qaeda propaganda videos and terrorist instruction manuals. The forums Qalah, al-Shamikh, Majahden, and al-Faloja are especially popular among terrorist cells, and new recruits are encouraged to refer to the sites to read the jihadist literature. These chat rooms also aim to convince prospective members to join or to stage personal suicide attacks.

According to the Search for International Terrorist Entities' (SITE) special report on Western Jihadist Forums, during 2009 several notable technical changes occurred in many of the jihadist forums (SITE, 2009). Thus, for example, the long offline, prominent English-language jihadist forum, al-Firdaws English, returned on 24 May 2009. The newly resurrected al-Firdaws English forum is open to the public, rather than being password protected. Permitting nonmembers to view discussion and content on the forum is a significant departure for al-Firdaws style, as previous iterations of the forum have been both completely password protected and not open to new membership. The forum administration's decision to open the forum to public observation suggests that they may envision the forum containing less-sensitive information in the future. Despite allowing forum visitors to access threads and read content, al-Firdaws English remains closed to new and prospective members.

The case of Younes Tsouli is especially demonstrative of the resourceful uses of the Internet by Internet-savvy terrorists. Tsouli, more commonly known by his Internet pseudonym *Irhabi 007*, illustrated perfectly how terrorists are using the Internet not just to spread propaganda, but to organize attacks. Between 2003 and the time of his arrest in December 2007, *Irhabi 007* engaged in several instrumental activities on the Internet. In 2003, he began joining various terrorist Internet forums, where he uploaded and published pictures, videos, and instruction manuals on computer hacking. Shortly thereafter his skills were sought out by al-Qaeda leaders who wanted him to provide logistical support for their online operations, and in 2005, Tsouli became the administrator of the extremist Internet forum, al-Ansar, where he began publishing bomb-making instruction manuals and details related to suicide bombing operations. He helped Zarqawi's al-Qaeda faction in Iraq and became a central figure in enabling Zarqawi to reestablish the links between al-Qaeda-affiliated groups after the fall of the Taliban. *Irhabi 007* eventually hacked his way into an unprotected file directory on an Arkansas state government Web site. He then posted propaganda and beheading videos. Cyber-tracking Intelligence immediately noticed *Irhabi 007*'s perfect English and questioned the cybercriminal's nationality. Younis Tsouli was caught in 2006. On his home computer, British investigators found photos of locations in Washington D.C. that had been e-mailed to him by colleagues, which suggested that he was helping to organize a terrorist attack on Capitol Hill. Of course, after Tsouli was caught, other cyberterrorists learned from his mistake.

When Terrorists Tweet

A report released in 2008, by the US Army's 304th Military Intelligence team, examines the possible ways terrorists could use mobile and Web technologies such as the Global Positioning System, digital maps, and Twitter to plan and execute terrorist attacks. The report includes a chapter entitled the 'Potential for Terrorist Use of Twitter,' which expressed the Army's concern over the use of the blogging services. The report says that "Twitter is already used by some members to post and/or support extremist ideologies and pserspectives. Extremist and terrorist use of Twitter could evolve over time to reflect tactics that are already evolving in use by hacktivists and activists for surveillance. This could theoretically be combined with targeting" (The Army's 304th Military Intelligence OSINT Team, 2008: p. 8).

The report lays out three possible scenarios in which Twitter could become a terrorist tool: (1) using Twitter, terrorists can send and receive near real-time updates on the logistics of troops' movements in order to conduct more successful ambushes; (2) one operative with an explosive device or suicide belt uses Twitter to send images of his or her location to a second operative who can use the near actual-time imagery to time the precise moment to detonate the explosive device; and (3) a cyberterrorist operative finds a soldier's Twitter account, hacks into this account, and communicates with other soldiers under the stolen identity.

In his study on 'Online Jihad on Twitter,' Stalinsky (2011a) describes how Twitter is increasingly being used by terrorist organizations and their media outlets, and how their online followers are growing in number. One of the many terrorist groups now utilizing Twitter is al-Qaeda and its followers. After the deaths of Anwar al-Awlaki and Samir Khan were confirmed by al-Qaeda, online jihadi activists reacted by calling for flooding American Web sites and social networking sites including Twitter with their speeches, writings, and videos. A member of the Shumoukh al-Islam forum declared in English: "Together for Islamizing [the] U.S.A. I want to see the American forums, websites, YouTube channels, and Twitter full of Sheikh Anwar al-Awlaki's lectures and videos. It will be a curse chasing the Americans and their dogs." He added in Arabic: "To the lions of uploading and [online] distribution, to the students of Anwar al-Awlaki … I entrust you with supporting your brothers, the *mujahideen*, with this knowledge … we shall spread their actions and the truth … You are the hope of the *ummah*, you are the hope of jihad … Let it be a vengeance raid for our sheikh, al-Awlaki. We want a raid of every American forum, every Facebook page, every Twitter account …" (MEMRI, 2011).

There are multiple ways in which terrorist groups are using Twitter. Among them are sharing videos, 'tweeting' news flashes about attacks and battles, spreading propaganda, sharing operational instructions, and calls for action. One example of such use of Twitter is the British jihadist Anjem Choudary, spokesman for the banned Islam4UK organization, cofounder of al-Muhajiroun. On 19 March 2011, Choudary launched a Twitter account and began using Twitter for disseminating and linking to his videos on YouTube, for announcing collaboration with other jihadi groups, and for calling on his followers in the UK and the US for a return to the Caliphate; for *shari'a* law to replace the US Constitution; for Islam to conquer the White House and the UK; for Islam to take over the world; for Libyans to declare jihad and annex other countries; and for Allah to destroy the enemies of Islam, as well as praise for Anwar al-Awlaki and Osama bin Laden, and many more. Another example is the tweet of a Jihadi Twitter user, which called for readers to contribute and to make efforts to bring about the kidnapping of a US soldier. The item, tweeted on November 2011, followed a $1 million offer by a member of the Saudi royal family and by influential Saudi cleric Awadh al-Qarni for kidnapping Israeli soldiers. It should be noted that al-Qarni tweets prolifically (at http://twitter.com/#!/Dr_alqarnee) and has over 257 000 followers. As noted by Stalinsky (2011a), al-Qarni is only one of many Islamists and jihadists, who have begun using Twitter to spread their ideology. Some of the more notable groups and figures now actively Tweeting include the Taliban, Afghanistan, Abdulqahar Balkhui, Sheikh Yusuf al-Qaradhawi, the Muslim Brotherhood, Ikhwan Syria, Hamas, the Al Qassam Brigade in Palestine, Jihad al-Ansar Media, Nukhbat alI'lam al-Jihadi, Ribat Media Center, Hezbollah, the Somali al-Qaeda-affiliated al-Shabaab al-Mujahedeen, and many others.

Hezbollah, for example, began tweeting on 16 November 2011. In the first month since it launched its Twitter account, Hezbollah has posted 15 254 tweets – that is, over 400 tweets per day – and has 7339 followers. The tweets are in Arabic, French, and English. The tweets included statements by Hezbollah officials as well as news stories from the Middle East. Hezbollah uses Twitter tools such as AddThis, which bills itself as "the world's largest sharing and social insights platform. AddThis helps you integrate sharing tools into your

site, spread your content, and drive social traffic. In-depth analytics provide insight into your audience and their activity."

The Taliban commander Abdul Sattar Maiwandi, who is in charge of the Taliban's official web presence, gave in February 2011, a detailed interview to the Taliban's Arabic-language magazine, al-Somood. In the interview, he boasted of defeating the US in the media field and discussed the Taliban's online media campaign, including its presence on Twitter. As part of an apparent strategy by the Afghan Taliban to broaden their online reach by using social media, the organization has created several accounts on Twitter. The Taliban maintains several official Twitter accounts. The first, the Islamic Emirate of Afghanistan Twitter account, http://twitter.com/#!/alemarahweb, was created on 19 December 2010, and posted 1998 'tweets,' many of them, announcements of attacks on US and coalition forces. Thus, for example, among the tweets posted to this account were those dated 13 September 2011, when Taliban insurgents attacked two symbols of the US diplomatic and military presence in Kabul – the US embassy and NATO headquarters. They included minute-by-minute updates on the attack, detailing the killing of US soldiers. The other Taliban Twitter account, http://twitter.com/#!/ABalkhi, was created on 12 May 2011; it has posted 537 tweets and has 1663 followers. It describes itself as 'The Islamic Emirate of Afghanistan, News, Interviews, Analysis, Statements' and links to the official Taliban Web site. The Taliban's use of Twitter is rather sophisticated; it uses services and applications such as FeedTwit, which sends RSS feeds to Twitter by direct message. This can be used by the Taliban fighters in the field to communicate with each other directly using their phones, rather than via the Internet or e-mail.

al-Qaeda's most important English-language forum Ansar al-Mujahideen English Forum (AMEF) is also very active on Twitter; its Twitter efforts are supported by an entire network of online activists and groups (Stalinsky, 2012). AMEF is considered the primary English-language jihadi forum, disseminating the majority of al-Qaeda's propaganda for the English-speaking West. On 27 October 2011, AMEF opened a Twitter account, and has since then posted over thousand tweets, approximately a dozen per day. The AMEF tweets focus on jihad news, from fronts in Afghanistan, Pakistan, Iraq, Russia, Kazakhstan, Dagestan, Syria, Somalia, Kenya, Libya, Uzbekistan, Albania, Bosnia, and the West. They include links to speeches and videos of al-Qaeda leader Ayman al-Zawahiri, and of Abu Yahya al-Libi, Anwar al-Awlaki, Abu Muhammad al-Maqdisi, and other jihadist leaders. Tweeted by AMEF include: al-Qaeda Central, al-Qaeda in the Arabian Peninsula (AQAP), al-Shabab, al-Qaeda in the Islamic Maghreb (AQIM), Taliban, Tehreek e-Taliban Pakistan, Islamic State of Iraq (ISI), Jund al-Khilafa, Abdullah Azzam Brigades, Boko Haram, Fath al-Islam, Ansar al-Jihad in the Sinai Peninsula, Abu Sayyaf Brigades in the Philippines, Islamic Party of Turkestan, and Western Islamists such as Anjem Choudary of Sharia4UK, Muslims Against Crusaders, Shariah 4 Belguim, Hani Sibai, and others.

Finally, 'Asad al-Jihad 2,' a prominent member of the jihadist online community, confirmed in June 2012 his new Twitter account. This message details the benefits of using Twitter to reach followers and present material without a media spin: "As everyone knows, Twitter is a very important arena for public and private media, and this arena holds the segment of people with whom we can deal and keep in touch. This is an important step in breaking the media barriers that were placed by the enemies of Islam against the people of the truth, and were made to stand between them and the public in the Ummah with their different inclinations" (SITE, 2012).

Terrorists on Facebook

Membership within the international Facebook community has boomed in recent years. Facebook is currently the world's most popular social networking Web site with an estimated 900 million users worldwide. Terrorists have taken note of the trend and have set up profiles as well. There are numerous Facebook groups declaring support for paramilitary and nationalist groups that were designated as terrorist organizations by most Western nations. Before the widespread adoption of social networking platforms like Facebook, individuals had to visit dedicated jihadist Web sites or forums in order to learn about the state of jihad in the world, the status of jihadist groups, and tools and tactics for carrying out jihad. Today, however, one can instead simply go to a Facebook page or a YouTube video to consume jihadist content. Facebook is clearly filling niches once reserved for jihadist official Web sites and forums. The US Department of Homeland Security (DHS) report, 'Terrorist Use of Social Networking Sites: Facebook Case Study,' notes that although terrorists have been using social networking sites for quite some time, their strategies for exploiting Facebook have evolved and that they have learned 'the inherent value in exploiting a nonideological medium' (DHS, 2010). According to the DHS report, terrorists and jihadists use Facebook for numerous purposes: as a way to share operational and tactical information, including bomb recipes and weapons maintenance; as a gateway to extremist forums; as a media outlet for propaganda; and as a source of remote reconnaissance for targeting purposes.

In December 2008, jihadist started online calls for 'Facebook Invasion.' The first call was posted on al-Fallujah, a password-protected jihadist forum. The author hopes to reach Muslims and Americans, and 'fight the media offensive on jihadist media, its forums, and its Web sites.' He provides a synopsis of Facebook and its growth since founding, noting the number of its users and reach. The posting also explains how jihadists can use Facebook and presents images detailing the registration process, adding friends, and setting up groups. The goals of the 'Facebook Invasion' according to the text are "(1) Reaching the vast base of Muslims who subscribe to Facebook; (2) Encouraging the brothers to create new media tools on the Internet in order to support jihadist media; (3) Creating a solid foundation on Facebook and shedding light on it as a media tool to reach people; (4) Moving from the elite community (jihadist forums and sites) to Muslims in general, participating and interacting with them; (5) Developing media work and encouraging its creativity, renewal, flexibility, and change; (6) Reaching big portions among the Crusaders, broadcasting losses of their armies, revealing the lies of their commanders, and urging Muslims to fight them." Later that month, a group calling itself, 'Knights of Support Invasion 2,' appeared on Facebook. The group is comprised of seven

brigades each tasked with distributing and promoting Salafist doctrine and mujahideen propaganda. The seven brigades include a Shariah Brigade, English Media Brigade, Martyrs and Prisoners Brigade, and Media and Design Brigade.

A year later, in December 2009, determined to strengthen the 'Facebook Invasion' and ensure its success, a posting on al-Fallujah jihadist explained the next stage of the 'Facebook Invasion' and how to fix errors discovered in prior stages. The user explaining the third stage, 'Omar Abdul Hakim,' suggests how a jihadist can start a group and recruit members, such as finding Muslims who share similar beliefs and interests, and slowly introducing them to jihadist propaganda. He gives specific advice how to communicate with Facebook users, providing a form letter that they may send, and also suggests steps to take while forming the group and what to do should the group be deleted, so as to resume activity.

Perhaps more than any other jihadist group, Hezbollah has learned to capitalize on Facebook's accessibility and global usage to reach a wider audience with its propaganda. As early as early 2008, Hezbollah had established a presence on Facebook, which has since ballooned into hundreds of pages, available in no fewer than nine languages, and with fans numbering in the tens of thousands. This network of Hezbollah pages on Facebook includes groups dedicated to Hezbollah itself as well as its leaders like Secretary General Hassan Nasrallah and helps to spread Hezbollah propaganda across the world. SITE Intelligence Group (2011a) documented the strong presence of Hezbollah on Facebook with dozens of pages dedicated to the group, reaching out to more than 100 000 fans. The international reach of Hezbollah on Facebook is evident in pages like the Indonesian-language 'Hizbullah,' founded 29 March 2010, which has attracted hundreds of fans, the Turkish-language 'Hizbullah,' founded 10 November 2010, and many more Hezbollah Facebook pages in French, Hebrew, Albanian, Spanish, Urdu, and Persian. The wide majority of Hezbollah Facebook pages, however, are in Arabic or English. Pages dedicated to Hezbollah leaders are numerous and very popular. An Arabic-language page dedicated to the deceased Mohammed Hussein Fadlallah, considered the spiritual mentor of Hezbollah, was founded in March 2008 and has gathered 23 400 fans till 2011. An English-language equivalent called 'Grand Ayatollah Sayed Fadlullah,' also founded in early 2008, has attracted 26 600 fans. Hezbollah's Secretary General Hassan Nasrallah has inspired many Facebook users. For instance, the English-language page 'Sayyed Hassan Nasrallah' has accumulated almost 1700 fans since its launching on 9 January 2011, while the Arabic-language 'Mercy Upon Sayyed Hassan Nasrallah' has nearly 1200 fans and was founded 23 February 2011.

The Palestinian Islamic Jihad (PIJ) is another designated terrorist organization that at least since early 2009 has been busy building a Facebook presence. PIJ has spawned a large network of Arabic-language Facebook pages, which has attracted fans across nearly 50 Facebook pages. PIJ's Facebook pages include those dedicated to the group itself, its militant wing – al-Quds Brigade, and its founder, Fat'hi al-Shaqaqi. The pages feature official PIJ propaganda, such as videos and flyers, as well as incitements to jihad, military communiqués, and claims of attacks. The pages described here are "In Memory of the Martyrdom of Dr Fat'hi al-Shaqaqi," "Who Lives the Martyrdom, It is al-Quds Brigade," "Lovers of the Movement of Islamic Jihad – Lebanon," "The Islamic Jihad Movement (Nasirat Neighborhood)," "The Islamic Jihad Movement in Palestine," and "Lovers of the Martyrs of al-Quds Brigade."

In response to the killing of bin Laden on 1 May 2011, a popular and active 'We Are All Usama Bin Laden' fan page on the Facebook emerged. Before the page was removed from Facebook, the group contained nearly 30 000 members who posted hundreds of messages each hour. The page featured videos, poems, and reactions commemorating Osama bin Laden, as well as incitements for retaliation. Facebook users active on the page shared their reactions to bin Laden's death, giving brief eulogies, and encouraging readers to activism against Israel. Such networking on Facebook facilitates connections between groups and causes through linked content. Yet, while the original 'We Are All Usama bin Laden' page has been removed, hundreds of new pages replaced it, calling for attacks in retaliation for the death of the leader. Supporters of bin Laden and al-Qaeda have flooded Facebook with hundreds of fan pages and groups praising Osama bin Laden, nearly two hundred of which share the name 'We Are All Usama bin Laden.' These pages range in membership from less than ten up to several thousand Facebook users.

Facebook pages are also used to mirror terrorist Web sites: in 2011, a Facebook page was used for mirroring content found on the Arabic-language Ansar al-Mujahideen jihadist forum (Ansar). Ansar is a distribution point for al-Qaeda and affiliated jihadists. The Facebook page, 'Ansar al-Mujahideen Network,' thus also hosts the most recent releases from jihadist groups such as the Somali Shabaab al-Mujahideen Movement and the Afghan Taliban, and media groups including the Global Islamic Media Front and al-Nokhba Jihadi Media. Since its founding nearly 3 months ago, the page has amassed more than 3000 fans and has thousands of posts. To make sure that a new forum post is mirrored on Facebook, the page administrator set up an automated system using the 'RSS Graffiti' tool to link content automatically from Ansar. In this way, the Facebook page is directly updated from Ansar. According to the SITE report (2011b), the 'Ansar al-Mujahideen Network' Facebook page has ballooned in popularity, with thousands becoming fans of the page. The material on the group is exclusively comprised of jihadist material, with official communiqués and al-Qaeda releases directing readers to material published on the affiliated jihadist forum. Therefore, the Facebook page reflects al-Qaeda's ideology of global jihad and shares this propaganda with a larger audience, allowing them to reach potential new forum members as well as individuals who may be unable or unwilling to go to a jihadist forum.

The use of Facebook by terrorists is rather effective: in 2009, Deputy Director for Intelligence at the National Counterterrorism Center, Andrew Liepman, reported to Congress that the FBI is tracking a few Somali Americans from the Minneapolis area, who were reportedly recruited for the purpose of starting a US terrorist cell of the al-Shabaab faction through Facebook. Analysis of all recent cases of lone-wolf terrorists reveals that all these individuals were using new social media (e.g., Facebook, Twitter, YouTube, and more). The accused Fort Hood shooter, Nidal Hasan, exchanged Internet messages with Awlaki, while the Frankfurt terrorist Arid Uka, who confessed to the 2011

killing of two US airmen at the Frankfurt airport, had links with radical groups online using Facebook. For lone wolves, Facebook communication provides the needed social bonding, a (virtual) community, and a source of guidance, support and moral backing. The 2010 FBI arrest of Baltimore resident Antonio Martinez, aka Muhammad Hussain, who expressed his wish to die as a martyr on his Facebook page, highlights the use of Facebook as a tool for effective recruitment and indoctrination by jihad. "When are these crusaders gonna realize they can't win?" Martinez boasted on his Facebook page on 4 August 2010 "How many more lives are they willing to sacrifice. Allahhuakbar."

Terrorists can use this online social networking to monitor military personnel. In 2008, the Canadian Defense Department and the British Secret Service, M15, requested troops to remove personal details from social networking sites because of alleged monitoring by al-Qaeda operatives. US personnel are also warned about posting certain details or photos on their profile pages. Even if the information does not give details about the logistics of troop movements, it could potentially endanger the friends and relatives of the military and security personnel. Many soldiers unwittingly post detailed information about themselves, their careers, family members, date of birth, present locations, and photos of colleagues and weaponry. Canadian troops have been asked to exclude any information from their profiles that might even link them with the military. A report from the Lebanese capital of Beirut later that year stated that Hezbollah had been monitoring Facebook to find potentially sensitive information about Israeli military movements and intelligence that could be harmful to the national security of Israel. The report quoted an Israeli intelligence official saying that "Facebook is a major resource for terrorists, seeking to gather information on soldiers and IDF [Israel Defense Forces] units and the fear is soldiers might even unknowingly arrange to meet an Internet companion who in reality is a terrorist" (cited by Weimann, 2010: p. 25).

As terrorist groups increasingly use Facebook and other social networking Web sites to distribute propaganda and promulgate their ideology, they are also looking for ways to maintain their presence on these sites and not have their pages closed and accounts suspended: on 22 April 2011, a guide on how to 'effectively post' on Facebook appeared in Shumukh al-Islam forum. The 23-page guide opens with the following introduction:

> The Facebook website has become an important platform for spreading the true Islamic call that is represented in establishing the soul of jihad, raising up the Ummah, and getting out of weakness to strength and from loving the world and hating death to loving martyrdom and sacrifice in the Cause of Allah. However, the developments that have been integrated into the website have made posting on it to be more difficult than before. Accounts are being frozen after posting on one or two pages, thus letting our efforts go to waste. But thanks to Allah, no matter what cunning the owners of the site may try, Allah's cunning wins, and its result comes after relying on Allah and taking the means. Therefore, praise be to Allah, your brothers in the Shumukh al-Islam Network were able to overcome these obstacles, and this is what has been explained in this guidebook. We ask Allah on your behalf and ours to grant acceptance and martyrdom in His Cause.

The author, 'Abu Musab al-Dahik,' wrote that the problem is Facebook's antispam filter, and to circumvent the script, which will freeze an account that posts the same material to multiple pages, he suggested the user change the text of what they post. For his examples, he posted a video from the al-Qaeda-affiliated ISI to Facebook pages for Egypt and Gaza.

Yet, terrorists are well aware of the risks involved. A member of a Jihadi forum in English issued a warning, reminding readers that a Facebook network would allow security agencies to trace entire groups of jihadists, arguing:

> Don't make a network in Facebook … Then Kuffar will know every friend you have or had in the past. They will know location, how you look, what you like, they will know everything! Join Facebook if you want and use it to keep in touch with friends and brothers far away but not as a network.
> (SITE, 2009)

YouTube and They Tube

YouTube was established in February 2005 as an online repository facilitating the sharing of video content. YouTube claims to be the 'the world's most popular online video community.' According to Web site monitoring, YouTube's viewership in 2012 exceeded 4 billion video views per day and 1 h of video uploads per second. 70% of the traffic on YouTube comes from outside the US. While the first video on YouTube enjoyed 1.96 million views, the current most popular video (Justin Bieber's 'Baby') exceeded 521 million views. The exposure rates are even higher among younger people who spend many hours every day on YouTube watching, downloading, and uploading video clips. YouTube has faced criticism over the offensive content in some of its videos. All YouTube users can upload videos of up to 15 min duration each. Users who have a good track record of complying with the site's guidelines may be offered the ability to upload videos up to 12 h length. The uploading of videos containing defamation, pornography, and material encouraging criminal conduct is prohibited by YouTube's terms of service. In December 2010, YouTube added 'promotes terrorism' to the list of reasons that users can give when flagging a video as inappropriate. In October 2010, US Congressman Anthony Weiner urged YouTube to take down from its Web site videos of imam Anwar al-Awlaki, the Jihadi propagandist, saying that by hosting al-Awlaki's messages, "We are facilitating the recruitment of homegrown terror." British security minister Pauline Neville-Jones commented: "These Web sites would categorically not be allowed in the U.K. They incite cold-blooded murder, and as such are surely contrary to the public good."

Terrorist groups realized the potential of this easily accessed platform for the dissemination of their propaganda and radicalization videos. Terrorists themselves praised the usefulness of this new online apparatus; for example, convicted terrorist Younis Tsouli (so-called *Irhabi007*) testified (cited by S. O'Neil, 2007): "A lot of the funding that the brothers are getting is coming because of the videos. Imagine how many have gone after seeing the videos. Imagine how many have become shahid [martyrs]". In 2008, jihadists suggested a 'YouTube Invasion' to

support jihadist media and the administrators of al-Fajr-affiliated forums. This suggestion was posted on al-Faloja, a password-protected jihadist forum, on 25 November 2008. The posting provides a synopsis of the YouTube site and its founding, and notes its use by the US President-elect Barack Obama during his presidential campaign, and by others. YouTube is argued to be an alternative to television and a medium that allows jihadists to reach massive, global audiences. The message even instructs how jihadists should cut mujahedeen videos into 10-min chunks, as per YouTube's requirements, and upload them sequentially to the site. "I ask you, by Allah, as soon as you read this subject, to start recording on YouTube, and to start cutting and uploading and posting clips on the jihadist, Islamic, and general forums," said the posting on the jihadist Web site. "Shame the Crusaders by publishing videos showing their losses, which they hid for a long time."

Today, all terrorist groups have propaganda videos on YouTube. In 2008, Hamas allegedly launched its own video-sharing Web site (AqsaTube), although the group denied ownership of the site. AqsaTube, in addition to choosing a similar name, was designed to look just like YouTube and even copied its logo. Once certain Internet providers refused to host the Web site, Hamas launched a PaluTube and TubeZik. These videos are not meant to target local audiences alone but also to reach worldwide publics. More recent videos posted on these video-sharing Web sites are dubbed in English or have English subtitles. Hundreds of terrorist videos are uploaded to YouTube each day and because of the enormous volume of content, YouTube says it is impossible to prescreen each video before it is posted on the site. This caused Senator Lieberman to send, in May 2008, an official complaint to Google, the owner of YouTube, saying, "Google continues to allow the posting of videos by organizations the State Department has designated as Foreign Terrorist Organizations. No matter what their content, videos produced by terrorist organizations like al Qaeda, that are committed to attacking America and killing Americans, should not be tolerated. Google must reconsider its policy." The protest was not very effective: in 2010, Representative Anthony Weiner sent a letter to YouTube CEO Chad Hurley, calling for the removal of videos featuring al-Awlaki, dubbed the 'bin Laden of the Internet,' whose videos aim to find new recruits and promote radical Islamic extremism and violent jihad against Americans. al-Awlaki, has appeared in over 700 videos on YouTube with a combined 3.5 million views. Although YouTube, following government requests, removed Awlaki's videos, a simple keyword search for 'al-Awlaki' conducted in June 2012, brought up about 8000 video clips, most of them the audio and video recordings of Awlaki.

Propaganda videos from various al-Qaeda spinoffs and franchises are easily available, posted by AQAP, Al Qaeda in Yemen, AQIM, pro-Taliban groups, and more. The process is quite simple: the terrorists and their sympathizers or propagandists first obtain new videos from file-sharing sites. The videos are then uploaded to jihadist bulletin boards and web forums; users of these forums then typically upload the videos to YouTube and other commercial sites for mainstream consumption. Even when YouTube does remove videos after complaints, they are often reuploaded. Thomas Hegghammer, senior research fellow at the Norwegian Defense Research Establishment and editor of the Jihadica blog, notes that

> YouTube is extremely important for the dissemination of propaganda videos. I think YouTube is much more influential than bulletin boards because it reaches a much wider audience. Websites that specialise in jihadi propaganda are self-selecting in the sense that the people who access them are interested in jihadi propaganda to begin with. On YouTube, on the other hand, you can come across jihadi videos by accident, for example while searching for more moderate sermons. Basically, having jihadi propaganda on YouTube dramatically lowers the barrier of access.
>
> (Cited in The Java Report, 2010)

A study conducted by Conway and McInerney analyzed the online supporters of jihad-promoting video content on YouTube, focusing on those posting and commenting on martyr-promoting material from Iraq (Conway and McInerney, 2008). The findings suggest that the majority are younger than 35 years of age and reside outside the Middle East and North Africa, with the largest percentage of supporters located in the United States. As the researchers concluded (2008: p. 117): "What is clearly evident, however, is that jihadist content is spreading far beyond traditional jihadist websites or even dedicated forums to embrace, in particular, video sharing and social networking – both hallmarks of Web 2.0 – and thus extending their reach far beyond what may be conceived as their core support base in the Middle East and North Africa region to Diaspora populations, converts, and political sympathizers."

Terrorists and their followers are very resourceful about bypassing YouTube rules and bans. In April 2001, members of the password-protected English-language AMEF shared strategies for evading YouTube censorship of materials promoting jihad. Online responses provided techniques for rendering jihadist content less conspicuous to YouTube administrators and individuals who search for jihadist content to report, and also gave strategies to make creating new accounts easier and minimize the loss of contacts and information after accounts are removed. One suggestion was to keep two separate accounts, one for collecting previously uploaded material for friends and a second for uploading jihadist videos.

In recent years, Jihadi groups have begun free web hosting, where content, including large videos, can be uploaded anonymously and at no cost. One such 'invasion' was to the Internet Archive. Founded in 1996, the Internet Archive nonprofit organization whose stated mission is 'universal access to all knowledge.' The Internet Archive is recognized by the state of California as a library, and is a member of the American Library Association. As Stalinsky (2011b) revealed, "Al-Qaeda and other groups are continually and increasingly using the Internet Archive to spread their propaganda/recruitment messages, including video and audio recordings of speeches, attacks, publications, and much more. They often include content encouraging, and urging, terrorist attacks against America … Content is uploaded to and downloaded from the Internet Archive by jihadists daily."

Conclusion

Paradoxically, the most innovative network of communication developed by the West with its numerous online networking platforms – now serves the interests of the greatest foe of the West, namely, international terrorism. Much of the original online terrorist content used to be one-directional, text-based, in the form of traditional Web sites with a heavy reliance on text and messages posted on forums. However, technological advances, particularly the increased availability of sophisticated, but cheap and easy to use, video capturing hardware (e.g., hand-held digital video cameras, mobile telephones, etc.,) and interactive online networking platforms (e.g., Facebook) changed terrorist online communications. The global community created by social networks and interactive forums on the Internet is advancing cultural awareness and reconciliation efforts, but it is also advancing terrorists' goal to share its extremist messages to global audiences. By using these online communities to their advantage, not only can terrorists promote global paranoia, share their messages with sympathizers and obtain donations, but also create more terrorists. The Internet has provided terrorists with a whole new virtual realm to conduct their most sinister transactions. Terrorist groups are no longer confined to specific regional boundaries. Now terrorist networks can recruit the members located in any part of the globe. A person in the United States can literally take a terrorist training course within the privacy of their bedroom.

The interactive capabilities of the Internet, like chat rooms, social networking sites, video-sharing sites, and online communities, allow terrorists to assume an offensive position. Instead of waiting for web-surfers to come across their Web sites and propaganda materials, terrorists can now lure targeted individuals to the sites. The best way to persuade individuals to support your cause is to create an emotional, psychological, or intellectual bond with the targeted individual. The online social networking provides terrorists with an ideal platform to attract, seduce, teach, radicalize, train, and activate individuals all over the world.

Media-oriented terrorism has presented a tough challenge to democratic societies and their liberal values. The threat is not limited to media manipulation and psychological warfare launched by terrorists; it also includes the danger of restrictions imposed on the freedom of the press and freedom of expression by those who try to fight terrorism. These developments could wind up having profound implications for democracies and their values, adding heavy prices in terms of civil liberties to the destructive effects of terrorism.

Abstract

Terrorism can be considered to be a violent strategy which aims to provoke public and political reactions in order to bring about political change. Such politically aggressive approaches have a long history that predates today's experiences. Throughout this history, the beliefs that terror groups hold, the locations where they are formed, the reasons that people join and remain within groups, and ultimately why they leave have been diverse. Yet contemporary public, academic, and political attention and understanding of terrorism is frequently viewed through the prism of the September 2001 attacks on America. In turn the American-led response under the umbrella of the 'war on terror' has been instrumental in changing how counterterrorism is considered and the legitimacy of government-led attacks.

Introduction

Terrorism is an intentional form of violence that involves targeted attacks which are designed to intentionally scare, intimidate, to 'terrorize' for a political purpose. Attacks are usually directed at immediate targets such as people, events, or institutions and a wider audience whom protagonists aim to intimidate, shock or threaten. By so doing, terror groups intend to arouse support for their political discourse while undermining rival, usually dominant, ideologies as part of an overarching strategy to win concessions or defeat the declared enemy. These forms of political violence can be relatively inexpensive and undertaken by small numbers of activists. Hence acts of terrorism are considered to be a form of asymmetrical warfare, committed by marginalized groups who often resort to such tactics because they lack more conventional political resources and avenues for engagement. However, this opinion overlooks the strategic, clandestine use of violence by national governments or their complicit supporters. Such government actions are usually classified under the reactive heading of 'counterterrorism.'

Since September 2001, perceptions of terrorism have been dominated by impressions of contemporary 'Islamic' groups. Yet terrorism is a well established strategy that has been implemented by groups across the ideological spectrum and historical periods.

Defining Terrorism

Achieving a universally recognized definition of terrorism has proved impossible and has led to multiple interpretations. Schmid's (1984) seminal study identified 109 different definitions and distinct arenas of classifications such as state, public, and academic. He concluded that none of the definitions would satisfy the multitude of interested parties. There are a number of reasons for this morass. The main factors revolve around moral and power impositions which, Crenshaw (2011) notes, have pejorative connotations. The normative struggle over semantics has correlated with the shift in the struggle over propaganda and the wider perception of terrorism as an illegitimate strategy and the appropriateness of targets. Weinberg et al. (2012) trace this to Menachem Begin's decision, when leader of the Zionist Irgun, to describe followers as 'freedom fighters.' In the process he unintentionally contributed to one of the unwritten rules that articles on defining terrorism must refer to the adage that "one man's terrorist is another's freedom fighter." The credibility of such an application is generally easier if the cause is connected to a struggle for independence and/or is against authoritarian regimes and the denial of liberties.

Consequently the authority and ability to attribute actions as terrorism, counterterrorism, or tactic of war helps to shape the extent to which those actions are viewed as justifiable. The successful application of the label of terrorism can then be integral into how those groups are considered. In essence, the strategy and the negative connotations would become the defining characteristic of the group. This places groups, and conversely the labeling governments, in ambiguous positions. At one level, being classified according to the act of violence strengthens the impression of groups' capabilities and helps in their attempts to 'terrorize.' Yet the inflation of the violent, unacceptable threat isolates the incident from the longer term political aims. The focus is upon the emotive reactions of the targeted audience rather than their considered reflection. In so doing, groups are defined by the perceived irrational outburst of violence and not the rationality of their discourse. The wider empathetic interest in the groups' agenda, which is required if they are to extend their opposition and achieve long-term aims, is therefore compromised. By comparison, during periods when the term was much less value-laden, earlier protagonists were less reticent when describing their actions as terrorism.

History of Terrorism

The term terrorism first came to prominence during the French Revolution in reference to the 'Reign of Terror.' However behavior that fits within definitions of terrorism can be identified throughout human history. Particular examples with semantic legacies include the 'Hindu' Thugees (Thugs), the Muslim Ismailis-Nizari or Hashashins (Assassins), and 'Jewish'

Zealot-Sicarii (Zealots). The Thugees are widely believed to have been involved in strangling anywhere between five lakh and one million people between seventh and nineteenth centuries (Rapoport, 2012). By comparison with the Thugs, the Assassins (1090–1275) had a political agenda that relied upon assassination. Daggers were their weapon of choice. Assassins aimed to purify Islam and reintegrate political and religious institutions between the eleventh and thirteenth centuries. Targeted killing allied to the expected capture and death of the perpetrator aroused considerable interest which at times threatened to overwhelm several governments. The utilization by both the Assassins and Zealots of religious doctrine was to have longer lasting impacts. Although the Zealots were only active for around 25 years in the first century AD their impact continues to resonate. Attempts to instigate Jewish rebellion against the large Greek population and the governing Romans failed spectacularly and ultimately contributed to exile. These experiences have become embedded within Jewish consciousness and continue to have a profound impact.

Despite the long history, the tracing of contemporary terrorism tends to stop at nineteenth century influential theorists such as German migrants Karl Heinzen and Johann Most, Russian anarchists, and Irish republicans. Tactics ranged from selective assassinations to indiscriminate bombing and what became known as 'propaganda of the deed.' Hence the action would both scare opponents and mobilize support. Terrorism became a strategy to challenge and overthrow governments. Ideas and tactics from this era were to influence subsequent generations and to inform the approaches of other groups. Rapoport (2012) categorized these forebears within an anarchist wave. Subsequent waves incorporated an anticolonial phase during which liberation movements in colonies such as Algeria, Cyprus, Kenya, and Palestine sought independence from European dominance. He argues that this was followed by the 'New Left wave' and the 'red' groups from Italy, Japan, the United States, and West Germany. A fourth religious phase followed to account for the rise of terror groups such as the Aum Supreme Truth who sought to kill thousands in the 1995 Tokyo underground sarin gas attack and militant Islamic groups such as al-Qa'ida. The precision within the wave classification is not without problems. In particular, the phases overlook earlier secessionists in Ireland and India, continuing nationalist inspired attacks in places such as Armenia, the Basque region, Bengal, Philippines, and Sri Lanka, preceding religious attacks in Saudi Arabia, Kashmir, Khalistan, and ideological actions in the name of left and right wing discourses in South America. Nevertheless emphasis upon a historical trajectory challenges the tendency to stress the novelty of contemporary forms of terrorism. In other words, terrorism did not begin on 11 September 2001.

Methods and Targets

Forms of terrorism tend to be partly determined by location, availability, histories of violence, and calculations over means and ends. Jenkins (1985: 17) remarks that tactics fall into three categories, namely "Terrorists blow up things, kill people, or seize hostages." Groups can adopt a range of tactics or become specialists, associated with particular methods. Nineteenth century Russian anarchists tended to rely on assassinations and gained considerable notoriety through killing prominent figures such as Czar Alexander II in 1881 and throughout the oncoming 'decade of regicide' (1882–1901). Subsequently assassinations were to become associated with the Italian revolutionaries who also became known for indiscriminate thrown bombs into cafes and later the Greek 17 November group who utilized assassinations through three-people scooter teams. Latin American revolutionaries and Palestinian nationalists were recognized proponents of hostage taking in the late 1960s; a tactic revived and adapted by Chechen secessionists, Colombian Fuerzas Armadas Revolucionarias de Colombia (FARC), and Filipino Abu Sayyaf. Palestinian groups also became renowned for hijacking, particularly, planes. Arguably the most famous hijacker of the era was Leila Khaled whose fame proved detrimental to the role's clandestine activities. Ideological framing also influences the selection of targets. Webb and Cutter (2009) explore shifts in the U.S. attacks from left-wing attacks in the 1970s against more overtly capitalist sites to fundamentalist Christian targeting of abortion and women's health clinics during the 1980s and environmental and animal rights targets in the 2000s.

The evolution of tactics requires predecessors from whom to learn. Moreover strategic approaches are also influenced by the attitudes and reactions of targets and intended supporters. Over the last 30 years, considerable attention has been allotted to terrorists who willingly die for their cause. Muslim and Tamil groups have been most associated with suicide bombers. Stemming from the 1983 bombing of the U.S. embassy Pape (2005) documents the extensive use of suicide bombers. For Pape, such attacks are rational approaches in that they are strategic and bombers become intelligent devices. Cognition enhances the bombs' reactive capability to situations, creating the most devastation in comparison with more conventional forms of explosives.

Another form of terrorists' 'suicidal tactic' has been the hunger strike, most associated with Irish republicans during the 1980s. The histories of the struggles, which groups connected into, provided examples of political violence which continue to resonate and enabled subsequent actions to be positioned as justifiable and part of a longer term trajectory of opposition. Irish republicans were able to draw upon the history of hunger strikes and the interwoven symbolism of sacrifice within Catholicism. Similar connections can be noticed in other forms of self sacrifice. For groups associated with al-Qa'ida, the utilization of what was ostensibly the taking of one's own life, through explosion, also connected into a credible religious legacy that stemmed from the belief that death in the name of Allah was not suicide but martyrdom.

Because impressions are dominated by outcomes of attacks and the asymmetric and limited form of political violence, which terrorism tends to take, careful consideration has to be allocated to targets. If a small number of members are to arouse widespread fear, the impact has to resonate beyond the immediate target. Hence sites that have significant symbolism are more likely to have a wider effect if attacked. The Twin Towers are an obvious example of locations which were symbolic of American economic, cultural, and political strength. At an individual level the Russian revolutionary Sergei Nechaev argued in 1868 that when selecting targets, "the guiding principle must be the measure of service the person's

death will necessarily render the revolutionary cause" (cited in Vertigans, 2011: 113).

Following the Tokyo sarin and plane attacks on America in 2001, concerns have grown that a new stage of terror methods and mass casualties has been reached. Despite these fears, most groups remain bounded by the restraints of impact. In crude terms, if groups aim to attract support and achieve sustainable longer term goals, there is a limit on the extent of devastation that they can cause.

Purpose of Attacks

The immediate intention behind acts of terrorism is exemplified by the famous 2500-year-old proverb attributed to Sun Tzu, a Chinese military strategist, who declared 'Kill one, frighten 10 000.' Following the subsequent development of extensive, rapid forms of communication, the number of potential people to frighten has magnified considerably. Beyond this instant aim, Crenshaw (2011: 9) proposes attacks by terror groups are committed for five interrelated reasons:

1. to set the political agenda;
2. to undermine the opposing government's authority;
3. to provoke an overreaction;
4. to mobilize potential supporters; and
5. to coerce compliance.

Without acts of political violence, groups would struggle to achieve these goals and to this end terrorism can be effective. Issues are raised and discussed in public and political arenas which might otherwise be ignored. Moreover attacks undermine economic confidence and the legitimacy of governments' who are observed to be failing to meet their primary duty of protecting citizens. Facing a crisis of credibility and anxious populations, governments can indiscriminately overreact in haste to defeat the threat.

Conversely the outcomes of attacks create difficulties for terror groups and in particular how to justify associated death and devastation. A common tactic is to emphasize the reactionary nature of the strategy and to apportion blame to enemies who have forced the situation to arise. Heinzen helped to set up a template explanation which continues to be recycled, albeit usually less eloquently, when proposing in 1849 that

> The path to Humanity will pass through the zenith of Barbarity. Our enemies have made this principle a law of politics and we shall either have to observe this 'law,' follow this 'constitutional path' or be buried, and our freedom with us.
>
> cited in Vertigans, 2011: 28

The likelihood of the tactics being effective depends upon multiple factors. First is the extent to which groups' aims resonate with wider populations who have the potential to be mobilized into widespread opposition to governing forces. The second and interrelated factor is the government's counterterror response and the extent to which opposition has the freedom to organize.

Causes of Terrorism

A number of explanations are put forward for why people become terrorists. These can be broadly categorized into individualist and socioeconomic criteria.

Individualist explanations tend to be prevalent across populist swathes of populations which struggle to reconcile acts of terrorism with mainstream norms and values regarding the sanctity of life and the killing of the 'defenseless.' Hence the destructive impact of attacks informs impressions and leads to a strong association with terror groups and violence. Such forms of aggression can become the dominant, possibly, only association people have with the group. Against this framing, terrorists are associated with personal failings which range emotional vulnerability through to mental illness and onto irrational, bloodthirsty individuals. Emotional explanations tend to be particularly prominent within accounts for why females become involved in terrorism and which differs from analysis of male engagement. Common reasoning includes women's humiliations, trauma, and shame often allied to manipulation by male recruiters.

Within psychology the emphasis on individual traits led to a long-standing commitment to identify a terrorist 'personality.' Yet dating back from the period of the Russian anarchist Narodnaya Volya, as Venturi (cited in Crenshaw, 2011: 44) reports, "the policy of terrorism united many different characters and mentalities." Moreover, the emphasis on the bloodthirsty and the mentally ill loses sight of the controls that terrorists have to possess and conditions which are placed upon targets. As a member of the Italian 'red' Prima Linea explains, "it was only permissible to kill certain persons in accordance with particular rules" (cited in Vertigans, 2011:133).

At the end of the explanatory spectrum is causal reasoning which revolves around structural conditions such as poverty, education, and repression. Rationality tends to underpin such explanations which provide pragmatic, materialistic accounts for involvement. Calculated criterion is usually attributed to males rather than females. Crenshaw (2011) points out that these generic explanations are problematic, not least because the impacts of such factors are not restricted to individuals who become terrorists. Instead large sections of populations may experience the same conditions and yet do not become terrorists. The obvious example would be to point to the underrepresentation of women in groups yet who are disproportionately poorer and politically weaker than the overrepresented males. There are a number of reasons for this inverse correlation. These include the patterns of inequality and restricted opportunities that characterize particular societies that are replicated within terror groups. Hence females in locations as diverse as Saudi Arabia, Northern Ireland, and parts of the United States often do not learn the capabilities and attitudes that appeal to skilled occupations and terror groups. Nor do they possess the social relationships that facilitate entry into groups. And when females are part of groups, they are often reported to be in support, marginalized roles. Even within egalitarian red groups which included prominent female members such as the (West German) Red Army Faction's Ulrike Meinhof and Gudrun Ensslin, the Japanese Red Army's Shigenobu Fusako and the (American) Weather's Bernardine Dohrn, there have been reports of machismo and

sexism (MacDonald, 1991). Portrayals within media and academic coverage will often draw upon physical reference points and sexuality in the analysis.

When experiencing the wider structural factors, reactions can take numerous nonviolent forms. Individuals may become involved in other forms of protest, could be apathetic or might seek alternative forms of explanation or escapism. Attempts to generalize based upon such generic reasoning cannot explain why these people do not become terrorists. However as the post-September 2001 American conflagration of the 'war on terror' with a 'war on poverty' highlighted, these oversimplified causal connections continue to resonate and influence approaches to terrorism. Conversely although Western 'red' groups tended to position themselves as agitators on behalf of the dispossessed and exploited, members tended to originate from well-educated, relatively privileged backgrounds.

Within the response to the 'war on terror,' emphasis has also been placed upon the introduction of democratic arrangements as an antidote to terrorism. Such a stance may overestimate the passive consequences of democracy. Indeed a quick review of a number of the prominent groups over the last 40 years highlights activities which originated in (West) Germany, Italy, Japan, the United Kingdom, and the United States; in other words democratic nations are not immune to terrorism. Conversely repressive regimes and particular measures contribute to the formation of terror groups. Crenshaw (2011) outlines how severe government actions were instrumental in the development of terrorism in diverse locations such as Tzarist Russia and post-1960s Northern Ireland. The latter example was also notable because government constraints were imposed within a democratic nation. Hence the denial or obvious futility of other forms of political channels for change contributes to radicalization. Consequently both democracy and repression can both be contributory causes and potential solutions. Much depends upon preconditions and underlying processes.

Trigger Points

Particular events can often be described as 'triggers,' incidents which contribute to individuals becoming involved with terror groups. Examples include the deaths of like-minded protesters by government security forces, which led to members joining the (West German) Red Army Faction (Aust, 1987; Bougereau, 1981; Neidhardt, 1982; Varon, 2004) or the Waco tragedy, which influenced the Oklahoma bomber Timothy McVeigh (Michel and Herbeck, 2001; Serrano, 1998), and killing of family members by rival groups, which was a factor behind recruitment both to loyalist and republican groups, in Northern Ireland (McDonald and Cusack, 2005; Taylor, 2000; Toolis, 1995). Interrelated to these events can be the suppression of the wider social movement or ethnic group which tends to be associated with nationalist struggles in locations such as Chechnya, Sri Lanka, and Uighur struggles in East Turkestan, China. Other triggers include unfulfilled expectations where governments fail to meet hopes around policies such as Islamification in Sadat's Egypt and Saudi Arabia and vehemently opposed government decisions such as the American-led coalition's invasion of Iraq. Alongside these politicized events can be more mundane, personalized, or heightened emotions such as boredom, excitement, honor, self gratification, and comradeship. These emotions formulate within social processes which some groups utilize in order to enhance recruitment and often resonate within existing preconditions. For Horgan (2005) the likelihood of terrorism as a strategy emerging and the subsequent direction is heightened when triggering events combine with preconditions.

Preconditions

The likelihood that triggers will lead to terrorism seems to be influenced by societal preconditions (Crenshaw, 2011; Horgan, 2005, 2009). Examples include historical development, rapid structural transformations, weak governance, foreign interference, and levels of pacification and legitimacy of asymmetrical political violence. In essence, in some locations violence remains embedded within dispositions as a credible option for instigating change.

Locations with a history of political violence that continue to resonate will often provide the preconditional basis which combine with particular triggers. Hence the incorporation of political aggressive struggles within Chechen, Columbian, Palestinian territories, and American mid-West provides credible templates on which subsequent generations can draw. In these contexts common memories incorporate symbols, sites, victories, betrayals, and narratives provide frameworks through which triggers are interpreted and processed (Vertigans, 2008, 2011).

Wider Social Movements

Terror groups tend to emerge out of wider movements and particular ideological, ethnic, religious, and national issues or combinations thereof. Consequently there are multiple issues which lead both to mobilization of the broader levels of activism and ultimately the decision to shift toward a violent strategy.

The demographic representativeness of that movement and the extent to which groups maintain ties and share commonalities will have a huge impact on the life expectancy and possibility of successful outcomes. Mobilization can originate in wider movements such as civil rights in Northern Ireland, student activism in Japan, Christian Identity in the United States, and the first *Intifada* in the Palestinian territories. These movements raise the profiles of social, economic, and political problems and engender acceptance over the right to challenge the status quo. For reasons identified above, such as perceived failure and government repression, factions within the movement breakaway and formulate alternative strategies in order to overcome the frustrations, disillusionment, anger or failings of the wider movement. Violence can become a viable alternative. Hence individuals must progress through evolving processes. Members shift from participating in passive challenging movements to being advocates of more radical forms of activism including attending demonstrations, and then onto political violence. However, once the breach is formulated, the process can become condensed for subsequent members who

are informed by the perceived failings of the original wider movement and the example of group founders. Moreover, second generations of members onward are, as Crenshaw (2011) outlines, also reacting to government counterterror reactions to the initial burst of terrorism. These responses are often instrumental in contributing to a surge in membership, particularly when government behavior resembles the authoritarian or partial roles outlined within radical discourse.

Processes into Terrorism

The intent to scare has contributed to individual terrorists being transformed into societal and, through globalization, international folk devils. Osama bin Laden being the recent most notable example. However the stereotypes which such images help to inform detract from the social processes which led to the formation, maintenance, and ending of terrorism. Similarly it is important that the inclination to isolate terrorists according to individualist criteria and psychological weaknesses does not contribute to the failure to locate terrorism as generally being a group activity. Lone wolves of terrorism, who operate by themselves, maybe prominent within populist media but in reality tend to be much rarer.

Consequently rather than search for common individual dispositions, much more can be learned from exploring the social processes which contribute to terrorism. For instance, Crenshaw (2011: 46) argues "Interactions among members of the group may be more important in determining behavior than the psychological predispositions of individual members." Within the group, a "pattern of mutual reassurance, solidarity, and comradeship develops, in which the members of the group reinforce each other's self-righteousness, image of a hostile world, and sense of mission" (Crenshaw, 2011: 47). In locations where there is widespread acceptance of the terror groups discourse, if not their methods, such as within popular nationalist struggles the transformations of individuals who are marginalized by residence into violent behavior may not be unexpected. By comparison, when becoming involved in left-wing violent activism, the shifts which relatively privileged members undertook required substantial changes both in attitude and in behavior.

The transition into terrorism is also a two way process. Individuals must usually be willing to join and groups must want their membership. The latter distinction is often lost within a general assumption that terror groups will accept anyone. On the contrary, groups must select carefully. Recruits must be able to operate clandestinely, be incorporated within groups, maintain secrecy, be capable, to offer utilizable skills, and be trusted. Consequently individuals must be known to the group or to reliable gatekeepers who can vouch for them. In nationalist communities, there are channels of communication which contribute to controlled and informed access to terror groups through points of contact. By comparison, individuals lacking existing networks which extend into terror groups and restricted opportunities for interaction would struggle to join without a credible link. It is partly for this reason that the emphasis upon recruitment through the Internet is overstated because few groups would accept members without a form of trusted reference.

These social bonds help to generate forms of consciousness that enable individuals to shift from mainstream normative behavior to challenging norms and values that may well entail, the intended or otherwise, seclusion from previous dominant relationships. And in order to make this transition, individuals must learn both about political ideology and associated forms of violence and become sufficiently detached from previous conflicting loyalties and affective ties. During this process, individuals or groups targeted for attack can be depersonalized and dehumanized or existing perceptions reemphasized. Hence terror groups will refer to targets in animalistic terms such as pig, monster and governments will tend to reciprocate through their emphasis upon perpetrators. For the terror groups, nonhuman characteristics help to mobilize support and commitment to attacks. In turn governments explain attacks through reference to innate and ultimately deterministic evilness. Malešević (2010) draws upon the role of ideologies which legitimize killing in the name of truth, justice, and equality. Powerful narratives within discourses create demarcations which include and exclude around religious identity, political allegiance, national consciousness, and racial features. These divisions provide the parameters to enable individuals to overcome the tensions that exist within societies over the reverence of life and the necessity of creating death. However, the narrative has to resonate with contemporary experiences and/or historical memory. Individuals who shift toward political violence will do so for numerous reasons including their belief that the reasoning for attack is justified. Hence some Islamic group members will consider that the United States is trying to destroy Islam. By comparison, American white supremacists are convinced that Jews have taken over the country. Generally members of the different discursive groups tend to share a belief that their actions are altruistic and are implemented as part of a wider strategy in order to create a better society for their followers, both real and potential.

Contrary to the populist view of the innately evil and abnormal terrorist, such individuals are not 'natural' terrorists. Instead individuals have to learn about the radical discourse and how to be involved in acts of political violence. Within contemporary impressions of terrorism and the perceived dominance of 'Islamic' groups, education and in particular religious schools have been identified as primary causes of radicalization. Certainly a variety of schools in diverse locations such as Northern Ireland, the United States, and Saudi Arabia have contributed to perceptions of superiority, injustice, and separation. Again though as with the poverty causal explanation, millions of children are educated yet only a minority proceeds into terrorism. Education seems to be contributing to particular social dispositions and a wider precondition. Nevertheless in isolation, schools and universities are not conveyor belts for terrorism. Information is also acquired through a variety of media sources which can contribute to processes of radicalization. And within the media, considerable emphasis has been placed upon the role of the Internet in extending the terror threat. The Internet has become a useful tool of communication for terror groups and a potential source of recruitment. However there is a danger that the risks are overstated and the Internet becomes incorporated within the populist view that terrorists are brainwashed into joining groups. News items on a variety of medium do

influence views and values. However they only do so in the form of triggers, combining with preexisting conditions which provide the framework through which the event is interpreted.

Within nationalist settings, family members who share similar life experiences can often be instrumental in the formation of radical ideas. With more discursively orientated groups, peers can be more fundamental, particularly in societies in which they are more demarcated boundaries between generations. The formation and subsequent membership of left-wing groups in the late 1970s are particular examples of the prominence of peer groups. Within Italy, this happened during a period when modernization and secularization were contributing to a diminution of Catholicism, family constraints, and ties. Friendships became more integral to identity formation as younger people sought answers from like-minded people who were sharing similar experiences. And once potential members are part of groups which either develop into terror organizations or lead into such organizations, the social dynamics are integral to the decision-making with relation to joining, remaining, and ultimately whether to leave alive or to continue to risk imprisonment and death. For instance, members of paramilitary groups in Northern Ireland would often socialize together, meeting in pubs and clubs and members of Jemaah Islamiyah ate, played football, and did business together. Socializing within groups had two main consequences: First, it strengthens the bonds between members; second, it contributes to a weakening of ties outwith the group. Longer term outcomes can vary, depending in part upon the extent to which members become separated from the people they claim to represent. Groups became the emotional focal point of satisfactions and frustrations. In nationalist communities this is less evident. By comparison, some of the 'red' groups' clandestine and transient existence contributed to long periods of inactivity, boredom, isolation, and ultimately a critical distancing between their policy members and what the wider movement and intended supporters wanted.

Processes Which End Terrorism

Terrorism ends within particular locations for numerous reasons. Groups can be defeated through forms of counterterrorism which incorporate physical destruction, repression, imprisonment, or conversely through offers of amnesty for repentant terrorists. Alternatively groups may achieve their aims or at least obtain sufficient concessions to justify the end of the campaigns. Otherwise members may disengage voluntarily after becoming disillusioned with the tactics, lifestyle, or lack of success. For reasons of security and for the wider impressions of commitment levels that may arise, in some groups there is a reluctance to allow members to disengage of their own volition. And as with processes into terrorism, group dynamics are instrumental in decisions to leave, particularly if personal relationships form within groups that members want to prolong within more risk averse environments.

Often the intense relationships and loyalties to other members, alive or dead, can mean that there is an individual reluctance to leave. Solidarity with the group can exceed that of loyalty to the cause. Hence more widespread approaches to peace in civil wars can be adopted which incorporate disarmament, demobilization and reintegration. To be successful, related approaches have to be developed which encourage individuals to leave terrorism through the delegitimization of the radical discourse and/or show how life outside the group would be better than staying in the group. Education programs and employment prospects are integral to prospects for rehabilitation (Bjørgo and Horgan, 2009). Moreover, feelings of hatred and suspicion have to dissipate and be replaced by heightened levels of empathy and moderation. Arguably this is harder than more pragmatic learning and occupationally based approaches at reintegration. Shifts in emotions and the concomitant need for compromise and consensus require stability and security which generate over periods of time. And at this point, a cyclical process can become noticeable because the perceived lack of stability and security were factors in the original decision to join or form groups. Consequently repentance and commitment to pacification cannot be assumed to endure indefinitely if deep-rooted problems are left unresolved.

Conclusion

Contrary to the populist tendency to generalize terrorism and terrorists, groups form and different people join in different locations, for different reasons and with different intentions. They are united by their strategic use of terrorism as a short-term tactic to scare and intimidate and as a means to an end in order to achieve fundamental societal or global change. The routes and processes into terrorism are also diverse and often involve elements of mis/fortune that revolve around the locations in which individuals reside and the people who are integral to their social networks. Locations and networks allied to preconditions and triggers are instrumental in the likelihood that groups form and people join.

Beyond these similarities, there is striking heterogeneity between, and even, within groups. The multitude of discursive groups, regions where they form, issues that provide justification, and complex processes in and out of terrorism restrict the formation of generic explanations. Consequently approaches to prevent terror groups from forming, attacks from being committed, the defeat of groups, or to encourage member disengagement have to be nuanced and adapted to reflect the contextual, ideological, and discursive variations. As the unintended, terrorist reinforcing, consequences of counterterror approaches can indicate many governments struggle to achieve this degree of knowledge and understanding.

Abstract

Theories and findings on test anxiety are reviewed herein. Test anxiety has been researched extensively over the past 60 years. Findings show that test anxiety (1) comprises multiple affective, cognitive, physiological, and behavioral components; (2) is frequently experienced by students; (3) can negatively impact performance on complex and difficult tasks; and (4) is negatively related to students' academic achievement. Individual failure expectancies, overly high perceived importance of achievement, excessively high task demands, competitive educational structures, normative grading, and high-stakes testing contribute to test anxiety arousal. Psychotherapy and learning environments that strengthen students' competencies and self-confidence can alleviate test anxiety.

Test anxiety is a ubiquitous phenomenon in modern societies. Given that educational and occupational career opportunities are made contingent on individual achievement, attaining success and avoiding failure is vital for individuals across the life span. As a consequence, anxiety of failure is one of the most frequently experienced emotions around the globe today – an emotion that surfaces in various life domains, including education, work, and athletics. Anxiety of failure (or evaluative anxiety) is at the heart of achievement anxiety. Specific variants of achievement anxiety include test anxiety, mathematics anxiety, performance anxiety, competitive sports anxiety, and social–evaluative anxiety. Among these, test anxiety is certainly the most important construct in academic contexts (Cassady, 2010).

The relevance of test anxiety was recognized early in the twentieth century. At that time, psychoanalytical writers began to theorize about fear related to examinations (e.g., Stengel, 1936). Some of the first empirical investigations, including the development of a questionnaire measure of test anxiety, were conducted by J. Brown at the University of Chicago in the 1930s (Brown, 1938). The construct became popular after G. Mandler and S.B. Sarason (1952) published their seminal paper entitled 'A study of anxiety and learning.' Since then, over 1000 studies examining test anxiety have been published. Thanks to these studies, we have not only garnered cumulative evidence on the nature, functions, origins, and development of this emotion, but we have also learned how to successfully alleviate test anxiety by individual psychotherapy.

Concepts of Test Anxiety

Test anxiety is defined as the anxiety related to taking tests that is experienced before and during test taking (here, the term 'test' is broadly defined, including written and oral examinations). At the heart of this emotion is the fear of failing a test and of the consequences associated with failure. Similar to other emotions, test anxiety is comprised of a complex array of component processes. These processes can include (1) affective components in terms of uneasy, nervous feelings; (2) physiological components including physiological activation and symptoms such as increased heart rate, increased respiration rate, or sweating; (3) cognitive components involving worries about possible failure and its consequences; (4) motivational components in terms of motivation to avoid failure and impulses to escape from the situation; and (5) behavioral components in terms of facial and postural expression of anxiety. Although a prototypical case of intense test anxiety comprises all of these components, they are only loosely coupled, and not all of them need to be present in all episodes of test anxiety.

At the onset of research into this emotion, test anxiety was considered a unidimensional construct. Progress toward a more differentiated construct was made when Liebert and Morris (1967) proposed to distinguish the affective and physiological components of test anxiety (referred to as 'emotionality') from the cognitive components (referred to as 'worry'). Later, a number of additional distinctions were introduced, including I.G. Sarason's (1984) differentiation between affective tension, bodily symptoms, worry, and task-irrelevant thinking. Although scholars today agree that test anxiety is a multifaceted construct, opinions vary as to which facets best comprise this emotion.

Another important distinction within the test anxiety construct centers on distinguishing between habitual propensities to experience anxiety related to test taking and momentary episodes of anxiety experienced in a specific test taking situation. Using the distinction between trait and state emotions originally introduced by Cattell (1950), the former variant refers to trait test anxiety, and the latter variant to state test anxiety. Trait test anxiety is an individual's disposition to experience anxiety related to tests. Whenever a trait test-anxious individual is confronted with a test or examination, this disposition can manifest itself in the experience of momentary state anxiety. As such, trait test anxiety is best viewed as a contextualized personality trait.

Traditionally, it was assumed that trait test anxiety generalizes across various types of achievement situations. This assumption is challenged, however, by recent evidence showing that students' anxiety is more domain-specific than previously thought (Goetz et al., 2007). Similar to students' self-concepts of ability, correlations between students' anxiety tend to be low across domains such as math versus languages. Moreover, the available evidence shows that the domain

 http://dx.doi.org/10.1016/B978-0-08-097086-8.26064-9

specificity of students' anxiety increases with age. As such, dispositions to experience test anxiety may best be conceptualized as a hierarchy in which more generalized dispositions to experience this emotion are located at higher levels and domain-related dispositions (such as math test anxiety) are located at lower levels.

Assessment

The multicomponential nature of test anxiety implies that this emotion can be assessed using various methods. These include self-report, report by others, observation of facial and postural expression, analysis of peripheral physiological activation, and neuropsychological assessment of activation in central brain areas such as the amygdala. Among these methods, self-report techniques quickly gained popularity because of the ease with which they are administered in the classroom and because of their excellent psychometric properties.

Whereas J. Brown's (1938) early self-report questionnaire did not gain widespread attention, the Test Anxiety Questionnaire (TAQ) developed by G. Mandler and S.B. Sarason (1952) became the progenitor of the numerous self-report scales developed since then. Early instruments such as the TAQ measured test anxiety as a unidimensional construct. From early on, however, factor analyses showed that test anxiety scales do in fact represent more than one dimension. Following the distinction between the emotionality and worry components proposed by Liebert and Morris (1967), multidimensional instruments were developed. Examples are the Reactions-to-Tests instrument developed by I.G. Sarason (1984), Spielberger's (1980) Test Anxiety Inventory, and the integrative test anxiety scale proposed by Hodapp and Benson (1997).

As the assessment of achievement emotions has developed, it has been recognized that test anxiety is but one of several important test emotions deserving of empirical attention. Specifically, the Achievement Emotions Questionnaire (AEQ; Pekrun et al., 2004, 2011) makes it possible to examine test anxiety in the context of other test-related emotions including enjoyment, hope, pride, relief, anger, shame, and hopelessness. Confirmatory factor analyses of the AEQ scales have shown that test anxiety, although a unique emotion, is closely related to students' test-related shame and hopelessness (Pekrun et al., 2011).

Impact on Learning and Academic Achievement

Empirical Evidence

The link between test anxiety and learning has been studied in a large number of laboratory experiments and nonexperimental field studies (Hembree, 1988; Zeidner, 1998, 2014). Experimental studies have examined the effects of anxiety on performance on various types of cognitive tasks, including working memory tasks, mathematical problems, text comprehension, intelligence test items, complex problem solving, music performance, and sports performance. In general, the findings show the following pattern.

(1) Trait test-anxious students tend to perform less well on difficult or complex cognitive tasks than their less anxious counterparts. They tend to perform equally well or even better on tasks that are easy and less complex. (2) In experimental work, the detrimental effects of trait test anxiety are more pronounced when a task is introduced as a 'test' and involves ego-threat (e.g., when individuals believe they are working on an intelligence test). (3) State test anxiety experienced when performing complex and difficult tasks relates negatively to performance on these tasks. The relation is stronger for cognitive components of test anxiety (such as worries about failure) than for affective–physiological components.

Taken together, these findings indicate that anxiety impairs performance on difficult and complex tasks, but has null or even positive effects on performance on easy and less complex tasks. In line with the negative link between anxiety and complex task performance, (trait) test anxiety also tends to correlate negatively with students' academic achievement. The average correlations found in two meta-analyses were $r = -0.29$ (in grade 4 through postsecondary student samples; Hembree, 1988) and, for mathematics achievement specifically, $r = -0.23$ (Schwarzer et al., 1989). In addition, meta-analyses found that test anxiety is also negatively correlated with performance on intelligence tests (average $r = -0.33$; Ackerman and Heggestad, 1997), and that general trait anxiety is negatively correlated with performance on creativity tasks (Byron and Khazanchi, 2011).

It is important to note, however, that the range of correlations across studies also included zero and positive coefficients. Moreover, although correlations did not differ significantly across genders (Schwarzer et al., 1989), they did vary across grade levels. In the *meta*-analysis by Hembree (1988), the link between anxiety and academic achievement was near zero at the beginning of elementary school and increased across the elementary school years.

Theoretical Explanations, Mediating Mechanisms, and Reciprocal Causation

Most accounts of test anxiety posit that the cognitive components of this emotion explain the extant empirical evidence. Rumination about failure is thought to consume cognitive resources in terms of attention and working memory capacity, thereby reducing the resources available for task performance – worries about possibly failing an examination prevent one from fully concentrating on the task. Such a reduction in resources in turn leads to deteriorated performance on complex or difficult tasks that put higher demands on these resources. This mechanism explains why anxiety reduces performance on these tasks, whereas performance on easy tasks remains unaffected. Attention-deficit and resource allocation models targeting this kind of mechanism were part of early theories of test anxiety (e.g., Mandler and Sarason, 1952) and continue to be one dominant theoretical paradigm.

More recent approaches to the study of test anxiety call attention to other mediating mechanisms and to alternative causal pathways. For instance, as addressed in Pekrun's (1992a, 2006) cognitive–motivational model of emotion effects, beyond impacting cognitive resources, anxiety can also affect students' motivation to learn, information processing, use of learning strategies, and self-regulation of learning. With

regard to *motivation*, anxiety is likely to reduce students' interest and intrinsic motivation to learn because it is not compatible with the enjoyment needed to develop interest-based motivation. On the other hand, anxiety can arouse strong motivation to invest effort to avoid failure. By implication, the overall effects of anxiety on motivation and effort can be variable.

The impact of anxiety on *learning strategies* and *information processing* can be complex as well. In mood research, positive mood generally promotes top-down, heuristic, and creative styles of thinking and a relational, global mode of processing information, whereas negative mood promotes bottom-up, detail-oriented, analytic styles of thinking that focus on item-specific, local details of information. Similar to negative mood, anxiety likely promotes more rigid learning strategies that focus on rehearsal and the details of learning materials, and undermines the use of flexible cognitive strategies such as elaboration and organization of learning material and the use of metacognitive strategies such as flexible time management. In addition, anxiety can foster students' reliance on *external guidance for learning* and reduce their self-regulation of learning (Pekrun et al., 2011). Depending on the type of task and context, these effects can either undermine or promote academic task performance.

Moreover, for interpreting correlational links between test anxiety and academic performance, reciprocal causation of anxiety and performance should be taken into account. Though the correlations between anxiety and achievement can be due to negative effects of anxiety on students' performance, the reverse causal direction can play a role as well – low academic performance can trigger subsequent anxiety before and during examinations (*developmental model*; Meece et al., 1990; Pekrun, 1992b). In addition, performance deficits in test-anxious students can be caused by a lack of ability or a lack of study skills, implying that anxiety would reflect a lack of competences rather than serve as the cause of performance decrements (*skills deficit model*; Everson et al., 1989).

These various explanations should be viewed as complementary rather than mutually exclusive. In many students, lack of ability and/or learning skills and resulting academic failure may initially incite test anxiety. Subsequently, anxiety and lack of skills jointly impact students' performance trajectories by consuming cognitive resources, reducing intrinsic motivation, and deteriorating the quality of learning (e.g., use of suboptimal cognitive and metacognitive strategies). Overall, such feedback loops between anxiety and performance involve vicious cycles in which anxiety deteriorates performance and low performance further increases the level of anxiety.

A number of studies have shown that the effects of anxiety on achievement can indeed be due to a number of cognitive and motivational mechanisms (Pekrun et al., 2011; Zeidner, 1998, 2014). Multiple mechanisms involving differential effects on performance can also explain why some studies find zero or positive correlations with students' academic achievement instead of negative relations (Hembree, 1988; Schwarzer et al., 1989). Finally, the findings from a few longitudinal studies corroborate that anxiety and achievement are linked by reciprocal causation over time (Meece et al., 1990; Pekrun, 1992b; Schnabel, 1998).

Developmental Trajectories

For many students, the development of test anxiety can be traced back to the preschool years. Psychodynamic approaches suggest that overly high parental expectations and negative judgments, which produce feelings of dependency, guilt, aggression, and anxiety, can play a major role at this age (S.B. Sarason et al., 1960). Nevertheless, in early elementary school the average levels of test anxiety are still relatively low. Mean values increase over the elementary years, which is likely due to many students' emerging experiences with cumulative academic failures (Hembree, 1988; Wigfield and Eccles, 1989; Zeidner, 1998). This development is congruent with a decline in self-concepts of ability (Hembree, 1988). Moreover, correlations between test anxiety and achievement tend to become stronger at this stage, indicating that students' performance and their affective experiences begin to be linked more closely, as suggested by developmental models of the anxiety–achievement relationship.

After elementary school, average levels of test anxiety remain fairly stable throughout secondary school and college. Nevertheless, the individual student can still experience a substantial increase or decrease in test anxiety, indicating developmental plasticity. Specifically, levels of test anxiety can change due to transitions between schools or classrooms. For instance, transitions to a new group can involve changes in one's relative academic status in the group. Social comparison processes can enhance or diminish student's self-concepts of ability and achievement expectations, and thus affect their test anxiety (Zeidner, 1998).

Individual and Social Origins

Biological Factors and Individual Appraisals

In general, emotions can be caused and modulated by numerous individual factors. These include genetic dispositions, neurohormonal processes, cognitive appraisals, situational perceptions, and sensory feedback from facial, gestural, and postural expression (Davidson et al., 2003; Scherer et al., 2001). All of these factors are important for anxiety as well.

With regard to more distal, biological variables, individual differences in general trait anxiety can in part be explained by genetic factors. Up to 50% of the variance in trait anxiety may be due to genetic variance (Eley et al., 2003; van Beijsterveldt et al., 2004), suggesting that biologically determined dispositions also partially define students' propensity to react with worries and emotional arousal in stressful academic situations. More proximal variables that cause and modulate emotions include students' appraisals of their competencies and prospects to achieve. At school, students have to learn how to adapt to academic demands while preserving individual autonomy – a process inevitably guided by appraisals. These appraisals in turn shape students' affect and motivation, including their test anxiety.

Appraisal theories of test anxiety focus on the impact of threat-related appraisals. From the perspective of R.S. Lazarus's *transactional model of stress and anxiety* (Lazarus and Folkman, 1984), test anxiety is based on two kinds of appraisals. The *primary appraisal* pertains to the likelihood and subjective

importance of failure, and the *secondary appraisal* involves cognitively exploring possibilities to cope with the situation. Depending on the combined result of the two appraisals, different emotions can be aroused. Should one perceive threat of failure and insufficient means to control the threat, then anxiety is assumed to be instigated. Lazarus's analysis implies that test anxiety is aroused when two conditions are met: First, the individual must anticipate possible failure on a subjectively important, evaluative task, and second, the individual must doubt whether potential failure can be avoided.

In Pekrun's (1984, 1992b, 2006) *expectancy-value model of test anxiety*, these two assumptions are reconceptualized in terms of expectancies and values related to failure. The basic proposition of this model is that test anxiety is a function of the subjective likelihood (expectation) of failure and the subjective value of failure. Both components are posited to be necessary for the instigation of test anxiety. As such, if failure is avoidable or if the student is indifferent to the consequences of failure, then anxiety should not arise. Anxiety is proposed to be a curvilinear function of expectancy, and is expected to be replaced by hopelessness if failure is subjectively certain.

Typically, situational appraisals of these kinds are based on objective characteristics of the setting, such as the relative difficulty of examination material, but they are also influenced by students' achievement beliefs. These beliefs can take 'irrational' forms (Ellis, 1962), for example, when failure is appraised as likely despite high individual ability, or when failure on subjectively unimportant outcomes is perceived as undermining self-worth. Irrational beliefs can make students not only highly vulnerable to anxiety, but also to other, related negative emotions such as shame ("I am not allowed to fail. If I fail, I am a worthless person").

The available empirical evidence regarding appraisal antecedents of test anxiety is in line with these propositions. Test anxiety has been found to correlate positively with students' expectancies of failure, and negatively with their self-concepts of ability, academic self-efficacy expectations, and academic control beliefs (Hembree, 1988; Pekrun et al., 2004; Zeidner, 1998, 2007).

In addition, students' appraisals are shaped by their achievement goals. Mastery goals relate to task mastery and developing competence, and performance goals relate to one's performance relative to others. In addition, both types of goals can focus either on approaching positive outcomes (i.e., success) or avoiding negative outcomes (i.e., failure; Elliot and McGregor, 2001; Elliot et al., 2011). Specifically, performance-approach goals pertain to outperforming others, and performance-avoidance goals pertain to not doing worse than others. Given that performance-approach and performance-avoidance goals can focus students' attention on the controllability and values of normative academic success versus failure, respectively, it stands to reason that these goals also influence students' anxiety (Pekrun et al., 2006, 2009). In line with these hypotheses, research examining the relationship between achievement goals and anxiety consistently finds that students' performance-avoidance goals are positively related to their test anxiety scores (Linnenbrink and Pintrich, 2002; Pekrun et al., 2006, 2009).

The Role of Education

Students' appraisals are influenced by the social environment. Factors in the environment that impact failure expectancies and the perceived importance of tests and examinations likely contribute to students' test anxiety (Pekrun, 2006). These factors include learning environments in the classroom and the home, and the organization of tests and examinations.

Learning Environments

Lack of structure and clarity in classroom instruction, as well as excessively high task demands, relate to students' test anxiety (Zeidner, 1998). The effects of these factors are likely mediated by students' perceived lack of control and expectancies of failure (Pekrun, 1992b). Overly high achievement expectancies from important others, negative evaluation feedback, and negative consequences of failure also correlate positively with students' anxiety (Hembree, 1988).

Additionally, competition within the classroom is positively related to test anxiety – likely because competition reduces expectancies for success and increases the importance of avoiding failure (Zeidner, 1998). In contrast, in K-12 research, social support from parents and teachers and a cooperative classroom climate are uncorrelated with students' test anxiety scores (Hembree, 1988). Two explanations may account for these findings. First, coercive components of supportive behavior may counteract the beneficial effects of support (Helmke, 1983). Second, support and anxiety may be linked by negative feedback loops: Social support can alleviate anxiety (negative effect of support on anxiety), but anxiety can engender support (positive effect of support on anxiety), thus yielding an overall zero correlation.

Tests and Examinations

Lack of structure and transparency within examinations has been shown to also contribute to students' anxiety (Zeidner, 1998). The findings point to factors such as clarity concerning demands, materials, examination procedures, and grading standards as critical in the elicitation of test anxiety. Furthermore, open-ended test items are found to induce more anxiety than multiple-choice items. Because open-ended formats require more working memory capacity, the worry and task-irrelevant thinking associated with anxiety can consume cognitive resources needed for the task, in turn eliciting more threat and further debilitating performance in anxious students. Methods effective at reducing these effects include using multiple-choice formats and providing external aids, such as books and computers, because such practices reduce working memory load and the threat of failure.

Furthermore, classroom practices such as allowing students to choose the questions they respond to on a test, relaxing time constraints, and giving second chances (e.g., providing the option to retake a test or correct incorrect responses for make-up points) can also reduce students' test anxiety. These methods likely function to minimize anxiety by increasing students' perceived control and alleviating expectations of failure. Finally, high-stakes testing that includes long-term and often far-reaching consequences of failure (e.g., impeded educational and career trajectories) is also likely to contribute to students' anxiety. This implies that educators who aim to

prevent the development of test anxiety should indeed avoid these types of evaluations.

Emotion Regulation, Coping, and Therapy

Given that test anxiety can hinder well-being and achievement, students can and should attempt to regulate this emotion. In the emotions literature, the regulation of negative emotions, and of stressful situations which tax or exceed individual capabilities, is referred to as *coping* (Zeidner and Endler, 1996). More severe anxiety can be successfully managed by psychotherapy.

Emotion Regulation and Coping

Emotion regulation implies strengthening or maintaining adaptive emotions, and decreasing or preventing maladaptive emotions. Basic components include recognizing and understanding one's emotions, managing one's emotions, and using emotions for action (e.g., for studying). More specifically, emotion management can be achieved by targeting the symptoms of the emotion (*emotion-oriented regulation*), by changing underlying appraisals (*reappraisal*), by acquiring competences (*competence-oriented regulation*), and by selecting and shaping emotion-eliciting tasks and learning environments (*situation-oriented regulation*; Pekrun, 2006). Beyond regulatory competences pertaining to one's own emotions, emotional competences also comprise abilities to recognize, understand, manage, and use others' emotions. Overall, cognitive competences to regulate one's own and others' emotions constitute students' emotional intelligence (Matthews et al., 2002).

Coping with stress and anxiety is addressed by Lazarus' transactional stress model (Lazarus and Folkman, 1984). In this model, anxiety is thought to lead to attempts to cope with this emotion and/or the stress that caused it. Many taxonomies related to coping with anxiety have been proposed, and most of these conceptions differentiate between problem-oriented, emotion-oriented, and avoidant coping (Rost and Schermer, 1987; Zeidner and Endler, 1996; Skinner et al., 2003). Clearly, these categories overlap with the above-mentioned categories of emotion regulation.

Problem-oriented coping entails active attempts to change the situation that causes anxiety, such as employing learning strategies to acquire competencies. Problem-oriented coping related to examinations (e.g., preparing for an examination) can itself have adverse effects. For instance, merely dealing with exam material can arouse thoughts about an upcoming exam, which in turn can increase situational anxiety (Bolger, 1990). For most students, however, the beneficial long-term effects of improving competencies via problem-oriented coping likely outweigh any negative situational effects.

Emotion-oriented coping is aimed toward directly changing the experience of anxiety. Emotion-oriented strategies include (1) anxiety reduction by means of alcohol, nicotine, or pharmaceutical consumption, or by means of relaxation techniques; (2) reduction of emotional tension by simply accepting anxiety and the possibility of failure ('secondary control'; Morling and Evered, 2006); (3) induction of positive, anxiety-incompatible emotions (e.g., by using humor, music, or emotional support from others); and (4) cognitively reappraising the situation as more controllable or less subjectively important. Many of these strategies are effective at reducing anxiety, but some of them clearly have negative side effects.

Avoidance-oriented coping implies behaviorally or mentally escaping from an anxiety-inducing situation. This can be achieved by (1) searching for mental distraction by focusing attention on task-irrelevant contents; (2) procrastination, taking excessively long breaks, and cutting one's preparation short; and (3) truancy, examination-avoidance, and school withdrawal. Like emotion-oriented coping, these strategies can also lead to an immediate reduction in anxiety. However, avoiding the experience of anxiety can produce a detrimental increase in a less conscious form of emotional arousal occurring at the physiological level (Spangler et al., 2002). Moreover, such strategies leave the underlying factors contributing to the experience of anxiety untreated. In this way, these strategies can be detrimental for students' learning and future career prospects.

Psychotherapy

Individual test anxiety is treatable. Some of the treatments for test anxiety are among the most successful psychological therapies available, with effect sizes above $d = 1$ (Hembree, 1988). Similar to the various coping strategies, different treatments for test anxiety focus on different manifestations and antecedents of this emotion. These include: affective–physiological symptoms (emotion-oriented therapy), cognitive appraisals (cognitive therapy), and competence deficits caused by lack of strategies for learning (skills training; Zeidner, 1998).

Emotion-oriented therapy includes anxiety induction (e.g., flooding), biofeedback procedures, relaxation techniques (e.g., progressive muscle relaxation; Jacobson, 1938), and systematic desensitization. *Cognitive therapies* aim to modify anxiety-inducing control beliefs, values, and styles of self-related thinking. Examples are cognitive–attentional training, cognitive restructuring therapy, and stress-inoculation training. *Study-skills training* teaches students to understand and use learning strategies and problem-solving skills that promote academic success and thus decrease anxiety. Finally, *multimodal therapies* integrate different procedures to address different symptoms and antecedents of anxiety within one treatment.

Cognitive and multimodal therapies have proven especially effective at both reducing test anxiety and enhancing academic performance (Zeidner, 1998). Study-skills training can successfully reduce test anxiety in students with deficits in their learning strategies. Consistent with the arguments above, therapy focusing exclusively on emotion-oriented procedures has been shown to successfully reduce anxiety, but has proven less effective at improving academic achievement. These kinds of therapy address the affective and physiological components of anxiety, but not the underlying cognitive components of anxiety that are primarily responsible for the performance-debilitating effects of this emotion.

Abstract

Psychological test data for unidimensional psychological constructs (abilities, traits, …) have the form of data matrices with the rows corresponding to subjects and the columns corresponding to items and the entries being single graded codings (ratings) of reactions of subjects to items. The reactions are governed by response probabilities in the sense of probabilistic IRT (item response theory). The product set of subjects and items can be weakly ordered by the concept of stochastic dominance. A hierarchy of probabilistic measurement models (in the sense of representational measurement theory) is reported for those data. The response vectors of subjects (and items) determine a coordinate wise partial order. Two independence axioms (ISOP, isotonic probabilistic measurement structure) grant the construction of separate ordinal scales for subjects and items. An additional cancellation axiom (ADISOP) gives interval scales for subjects and items. An extension of cancellation to another independence axiom (CADISOP) gives an additional interval scale for response categories. All structures can be extended to linear structures for items and/or subjects. It is the essential advantage of the hierarchical organization of the models that each step of complexity can be tested separately and independently.

Psychological test theory invites the formulation and testing of methods of assigning numbers to individual's attributes, such as degrees of skills or personality traits. Measurement theory is the formal and logical theory of necessary and sufficient conditions of attributing measures to objects or events. It is astonishing that test theory is not usually treated as a special area of measurement theory. Test theory (modern test theory, item response theory, IRT) is probabilistic and concerned with the relation of response probabilities to latent traits. It usually neglects the measurement principles (relations and operations, homomorphisms) necessary to represent observations by numbers and their relations (with the exception of the principle of specific objectivity, see below). Usually a representation by an analytical model (see below) is postulated and statistical tests are given to test the adequacy of the representation of empirical data by the model (item characteristic function, parametric IRT). Measurement theory usually is deterministic and axiomatic and concentrates on relations and operations. The relations typically are qualitative or ordinal. How can measurement theory be made probabilistic? How can test theory be made concerned about logical relations and homomorphisms (structure preserving representations)?

The more recent development of nonparametric IRT (Hemker et al., 1997; Holland and Rosenbaum, 1986; Irtel and Schmalhofer, 1982; Junker, 1993; Junker and Ellis, 1997; Mokken, 1971; Rosenbaum, 1984; Scheiblechner, 1995, 1998, 1999; Stout, 1987, 1990) is closer to measurement theory. The authors specify empirically (statistically) testable criteria necessary for unidimensional representations of psychological test data.

Typical psychological tests consist of a set of items ($i = 1, 2, \ldots, k$) which are supposed to 'measure' a common (unidimensional) psychological trait (e.g., verbal, numerical, spatial … intelligence; neuroticism, depression, …), and to which the subject ($v = 1, 2, \ldots, n$) chooses one answer out of several ordered categories ($h = 0, 1, 2, \ldots, m$). In most cases the test performance of a subject is summarized by the Likert score (simple integer score) or the trivial scoring function: all answers are weighted equally with constant weights for categories and the weights are summed over items. A major advance over this naive procedure was made by parametric rating scale models inspired by Rasch's measurement theory. A well-known parametric IRT model for ordered response categories is the rating scale model (RSM).

$$P(x = h|v, i) = \frac{\exp(h(\theta_v - \beta_i)\varpi_h)}{\sum_{x=0}^{m} \exp(x(\theta_v - \beta_i)\varpi_i)}$$

$$\beta_i = \sum_l a_{il}\eta_l + c$$

(Andersen, 1977; Andrich, 1978; Masters, 1982) where x is the response category of the answer ($x = 0, 1, 2, \ldots, h, \ldots, m$), θ_v the subject (ability) parameter, β_i the item (difficulty) parameter (with possibly a linear model with respect to basic components η_l) and ϖ_h the response category (attractiveness) parameter (with the normalizations for uniqueness of parameterization $\sum_i \beta_i = 0, \varpi_0 = \varpi_l = 0, c = 0$).

Models like this are an improvement over simple integer scoring because the fit of the model can be tested by a conditional likelihood ratio statistic (and the fit of the linear item parameter model can be tested by an additional likelihood ratio test). Thus we may detect, for instance, that no such psychological trait as conjectured does exist (in the sense of the model) or that not all items belong to the same psychological trait, or that the scoring of the categories may depend on the item and so on. However, the logistic form of the category characteristic curve (CCC), the function describing the probability of choosing category x; Hemker et al., 1996), the existence of three scales (subjects, items, categories) and their additive concatenation, the response category as scoring function (factor h or x in the exponent) are postulated all at once, and if the model does not fit there is no (or little) evidence as to which assumptions are failing (the situation is much better concerning the linear model for the item parameter assuming that the basic model fits).

An essential advantage of the probabilistic measurement theoretic formulation of such models is that no such risky

[†] Deceased.

assumptions are necessary simultaneously in advance, that each step can be tested separately, and that those axioms can be identified which are possibly responsible for lack of fit. The test of the logistic form of the CCC and of the adequacy of the scoring function are rendered unnecessary by a measurement theoretic test model because no analytic CCC is assumed and there is no need of a scoring function (beyond an ordinal scale). The existence of ordinal scales for subjects and items can be tested separately from each other and independently of the postulation of an additive conjunction of interval scales for subject and item parameters (see for instance the exponent of the CCC of the RSM). Should the test of additive item and subject parameters be successful, we could then test an additive conjunction with an appropriately constructed scoring function (an interval scale for the response category scale). Independently of the outcome of the latter test, and separately from each other, we can test additive models for the item and subject parameters. In short, the advantages of measurement theoretic test models are the stepwise construction of a hierarchy of gradually more complex models, and an exact specification of the level at which the construction of the models possibly might fail.

Making Deterministic Axiomatic Structures Probabilistic

A successful translation of the deterministic axioms of a measurement structure into a probabilistic version grants the formal rigor of measurement structures while being at the same time probabilistic, i.e., provides a statistical theory for testing the validity of the model. Some possibilities of probabilization of axiomatic measurement structures are expounded by Heyer and Nideree. A version of a probabilistic additive conjoint structure will be given below (ADISOP, CADISOP). The most basic proposition of most measurement structures is that an object a is in some respect larger, more attractive, etc., than an object b, symbolically, $a \gtrsim b$, where the objects and the relation are assumed to be empirically observable and deterministic (for example, two weights and the turning of the scale of an idealized balance). How could this be translated into the single, inconsistent qualitative reactions (right–wrong, strongly refuse–strongly prefer) of subjects to single items? Falmagne (1979) suggested replacing $a \gtrsim b$ with the probability $P(a \gtrsim b)$ of observing a 'larger reaction' (for example, the judgment a is louder than b) upon repeated presentation of the pair (a, b) (or of observing a larger median reaction time, etc.). This is feasible for some psychophysical tasks, but totally impractical for usual psychological intelligence and personality tests where individually identifiable items reasonably can be presented only once to subjects (a repetition would change the meaning of the item). For these I suggest replacing the larger relation $a \gtrsim b$ or the probability of a larger relation $P(a \gtrsim b)$ with the relation of two probabilities, $P(X \leq x \mid a) \leq P(X \leq x \mid b)$, where $P(X \leq x \mid a)$ is the probability of observing a specified or 'smaller' reaction than x (for example, a predominantly right answer) on presentation of a. If there are more than two graded responses (rating scales, polytomous ordered response categories) available for items I suggest using the concept of stochastic dominance (see below). The probabilities are an intermediate layer intervening between the empirical and numerical relational system of a measurement structure (Roberts, 1979: p. 274) and even estimates from single observations turn out to be sufficient for statistical testing of larger restrictive measurement structures (for example, if a subject 'moderately agrees' to an item his cumulative probabilities of 'disagreeing' or 'moderately disagreeing' are set to 0 and his probabilities to 'moderately agree' or 'agree' are set to 1).

A stochastic variable W dominates a stochastic variable V, if the probability that W is smaller/equal than an arbitrary value x is smaller/equal to the probability that V is smaller/equal to x for all x, that is:

Definition. Stochastic dominance $\gtrsim$.

$$W \gtrsim V \Leftrightarrow F_w(x) \leq F_v(x) \quad \text{for all } x$$

where $F(x) = P(X \leq x)$

Definition. Strict stochastic dominance $\succ$.

$$W \succ V \Leftrightarrow F_w(x) \leq F_v(x) \quad \text{for all } x$$

and

$$F_w(x) < F_v(x) \text{ for at least one } x.$$

If $W \gtrsim V$ we also write $F_w(x) \gtrsim F_v(x)$ for the cumulative distribution functions (CDFS) and similarly for $\succ$.

As an example, the students of a lecture on statistics rate their attitude (preference/aversion) toward the usefulness of statistics for the understanding of psychology (U) (high/low), the importance of statistics for professional success (P) (important/unimportant), the time needed to learn statistics (T) (acceptable/annoying), and the work with formulae (F) (fascinating/disgusting) on a four point scale. The students reject formulae most, the time requirements for learning statistics next, and think more positively about the importance of statistics for professional success, and most for understanding psychology (Table 1).

If the preference (aversion) for one option stochastically dominates the preference (aversion) for another option, then the probability that the first option is accepted (rejected) is always greater than or equal to the probability that the second option is accepted (rejected) if the ordinal scale is dichotomised (transformed into a binary scale) at an arbitrary position. This invariance makes the stochastic order relation independent of a great variety of different empirical operationalizations (experimental arrangements for the determination of larger relations).

If the deterministic order relations are made probabilistic by the concept of stochastic dominance, then the concept of empirical verification and falsification of single relations by

Table 1 Stochastic dominance of variables, $F \gtrsim T \gtrsim P \gtrsim U$ (cumulative distribution functions: 1, positive; 2, moderately positive; 3, moderately negative; 4, negative)

	Rating			
Category	*1*	*2*	*3*	*4*
U	0.417	0.778	0.972	1.000
P	0.183	0.563	0.817	1.000
T	0.064	0.278	0.714	1.000
F	0.063	0.175	0.588	1.000

single observations must be replaced by statistical testing of order relations (Bartholomew, 1983; Robertson et al., 1988) and by the likelihood principle of model testing. Suppose we want to test the validity of the above order relation $F \gtrsim T \gtrsim P \gtrsim U$ for all subjects of a specified population. Then there are many nonparametric tests to test the null hypothesis of no differences and we can test the hypothesis of the same (similar) order of items for all subjects by testing samples from all relevant subpopulations of subjects; we can also calculate the likelihood of all possible orders and choose the maximum likelihood order.

The Construction of Ordinal Scales for Subjects and Items: the Isotonic Probabilistic (ISOP) Measurement Structure

The most basic level of the hierarchy of models for the construction of unidimensional scales for psychological traits is the construction of ordinal scales for subjects and/or items. The construction of two scales simultaneously for two sets of objects (e.g., subjects and items) has been referred to elsewhere as biscalability or biorder (Guttman scale). Because these concepts are not probabilistic or appropriate only in psychophysical contexts they are not reported here (but they presumably could be made probabilistic).

In the example of rating different aspects (items i) of a negative attitude toward statistics each subject v generates a response vector $\boldsymbol{x}_v = (x_{v1}, x_{v2}, x_{v3}, \ldots)$ of ratings of aversions for items 1, 2, 3, …. The subjects possibly are characterized by a unidimensional latent trait 'aversion against statistics.' The response distributions of the response variables X_{vi} of subjects $v = 1, 2, \ldots, n$ and items $i = 1, 2, \ldots, k$ can be ordered by stochastic dominance – but how can the subjects (items) be ordered? The response vectors of the subjects give no simple order of the subjects with respect to aversion against statistics. The order relation on the set of subjects (items) has to be defined by a new concept. We can say that one subject dominates another (with respect to aversion against statistics) if all his/her ratings are larger than or equal to the ratings of the other subject. Of course, many pairs of subjects will not be ordered by this relation (the order is partial). The subjects cannot be compared directly, but by means of their response vectors, i.e., by means of the items as instruments; and therefore the measurement structure is called an instrumental probabilistic pair comparison system (Irtel and Schmalhofer, 1982; bioorder).

The set of observed multidimensional polytomous response vectors $\boldsymbol{x} = (x_1, x_2, x_3, \ldots)$ ordered by the relation.

$$\boldsymbol{x} \text{ dominates } \boldsymbol{y} = x \gtrsim y \text{ iff } x_i \geq y_i \text{ for all } i$$

is a multidimensional coordinatewise partial order.

If several variables are stochastically ordered and their order coincides with a scalar parameter of their distributions then they are said to be *isotonic* (similarly ordered) in that parameter. That parameter may represent a known attribute of the variables or a scale value on a latest dimension (for example, aversion in **Table 1**).

Definition. Isotonicity. A family of variables X_i or distribution functions F_i depending on a parameter p_i is isotonic in p_i if $X_i \prec X_j \Leftrightarrow F_i(x) \geq F_j(x)$ for all x of $p_i \leq p_j$.

In order to be able to construct ordinal scales for the set of subjects and items we now extend the concept of isotonicity to a two-dimensional array of variables X_{vi}, for example the aversions of several subjects for a set of attitude items or the preferences of visitors for various holiday arrangements. This is achieved by the axioms of the ISOP measurement structure.

Let A be a set of subjects $v, w, \ldots$, and Q a set of items $i, j, \ldots$. We associate with the Cartesian product $A \times Q$ a family of random variables X_{vi} with distribution functions $F_{vi}(x) = P[X \leq x \mid v, i]$ defined on the set $X = \{x, x', x'', \ldots\}$ of categories (values) of an ordered dependent ('achievement') variable X.

Definition. A system $\langle A \times Q, F\rangle$ where F is a family of distribution functions on $A \times Q$ is weakly, independently ordered (an ISOP model) iff the following axioms are valid.

Axiom W1. *Weak subject independence* holds if the response distribution of subject v dominates the response distribution of subject w at item i, then the response distributions of v are not dominated by w at any other item j.

Axiom W2. *Weak item independence* holds if the response distribution of item i dominates the response distribution of item j for some subject v, then the response distributions of i are not dominated by j for any other subject w.

Axiom LI. *Local independence* holds if the probability of the response vector of a subject v is the product of the probabilities of the single responses

$$F(x_{v1}, x_{v2}, x_{v3}, \ldots | v) = F(x_{v1}|v)F(x_{v2}|v)F(x_{v3}|v)\ldots$$

(Scheiblechner, 1995, 1998).

We can write W1 in the form if $F(X_{vi}) \prec F(X_{wi})$ for some i, then $F(X_{vj}) \gtrsim F(X_{wj})$ for all j meaning that the stochastic dominance relations between subjects are similar (isotonic) for all items. Analogously for W2, the stochastic order of items is similar for all subjects and therefore independent of subjects (except for ties: Scheiblechner, 1995, 1998). The pair $\langle A \times Q, F\rangle$ is called an instrumental probabilistic pair comparison system. Axiom W1 orders subjects by the stochastic order of their distribution functions of reactions to items and states that the orders are independent from the specific items used, except for possible ties (subjects are similarly ordered by items). This independence of the orders of subjects of the items is the basis for the construction of the latent unidimensional subject ordinal scale or person parameter. Axiom W2 similarly states that the stochastic order of items is independent of subjects and this is the base of the item ordinal scale or item parameter. The axioms are independent and can be statistically tested independently of each other.

If the system of variables is an ISOP, then the distribution functions can be ordered, and there exist ordinal scales $\varphi_A(v)$ on the set of subjects, and $\varphi_Q(i)$ on the set of items, such that the distribution functions of the family X_{vi} of random variables are functions of the two ordinal scales (Scheiblechner, 1995):

$$F_{vi}(x) = F(x|\varphi_A(v), \varphi_Q(i))$$

where $\varphi_A(v)$ and $\varphi_Q(i)$ are ordinal scales.

The two ordinal scales are 'order independent relative to subsystems' (Scheiblechner, 1995), that is, the ordinal scale for subjects does not depend on the set of items and the ordinal scale for items does not depend on the set of subjects, both except for ties (the corresponding property is called specific

objectivity or sample independence in the logistic Rasch model; Andersen, 1995; Rasch, 1960).

The following implications of ISOP can be tested:

1. the validity of axiom W1 for each item and for the total test (= set of items);
2. the validity of axiom W2 for each response vector (subject) and for the total sample;
3. the validity of the coordinatewise partial order of response vectors for each subset of items of the test and for the total test;
4. the validity of the coordinatewise partial order implied by one part of the test for another part of the test; and
5. the validity of a large number of manifest partial and linear isotonicities.

Especially the facility to test separately the single axioms of the measurement structure and the separate tests for different parts and aspects (formal relations) of the data are a measurement theoretical advantage of the ISOP measurement structure.

The Construction of Interval Scales for Subjects and Items: the Additive Conjoint ISOP (ADISOP) and the Complete ADISOP (CADISOP)

The axioms of the ISOP model are sufficient for the construction of two separate unidimensional ordinal scales on the sets of subjects and items. We now strengthen the ISOP model by additional axioms in order to derive ordered metric/interval scales for subjects and items. First the ADISOP model is considered which is an ISOP model with a cancellation axiom added that relates the subject and item factors.

Definition. A probabilistic pair comparison system $\langle A \times Q, F_{vi}(x)\rangle$, where $F_{vi}(x)$ is a family of cumulative distribution functions defined on $A \times Q$, is an ADISOP iff the axioms of the ISOP model and the following axiom are satisfied.

Axiom Co. Validity of cancellation of subjects and items up to order o.

(Similar structures are the PACOME models, Falmagne, 1979). An explanation of cancellation up to order o is given in Scheiblechner (1999) and Scott (1964). It means that a reduction of the item parameter by an amount δ can be compensated by an increase in the subject parameter by the same amount δ. The subject and item parameters 'cancel.' Or if we attribute real values to subjects and items then the order of their sum is isotonic in the order of their distribution functions. For example, if the 'ability' parameter of subject v plus the 'easiness' parameter of item i is larger than or equal to the sum of the ability and easiness parameter of subject w and item j, then the distribution functions are isotonic in the sum, i.e., $F_{vi}(x) \precsim F_{wj}(x)$ and the reverse.

If the system $\langle \boldsymbol{A} \times \boldsymbol{Q}, \boldsymbol{P}\rangle$ is an ADISOP model then the order of the CDFs is identical to the order of the sums of the subject and item parameters, i.e., there exist real functions ϕ_A, ϕ_Q on A and Q and $\psi_{A\times Q}(v,i) = \phi_A(v) + \phi_Q(i)$ on $A \times Q$ such that for all $(v, i), (w, j) \in A \times Q$

$$\phi_A(v) + \phi_Q(i) < \phi_A(w) + \phi_Q(j) \Leftrightarrow F_{vi}(x) > F_{wj}(x)$$

for some x or $\Leftrightarrow$ $F_{vi}(x) \prec F_{wj}(x)$

The scales ϕ_A, ϕ_Q are unique up to positive linear transformations, i.e., they are interval scales if Axiom Co is valid up to arbitrary order o, and they are ordered metric scales if Co is valid up to the finite order $(\min\{n, k\} - 1)$ where n and k are the number of elements of A and Q, respectively. Ordered metric scales are unique up to monotonic transformations which leave invariant the order of the (finite number of) intervals. Ordered metric scales are approximations to interval scales. The cumulative response distribution functions on the product set of subjects and items

$$F_{vi}(x) = F(\varphi(x); \varphi_A(v) + \phi_Q(i))$$

are antitonic (do not increase) in $\psi_{A\times Q}(v,i) = \phi_A(v) + \phi_Q(i)$ and isotonic (do not decrease) in $\varphi(x)$, where $\varphi(x)$ is an arbitrary strictly isotonic function of x (i.e., is an ordinal scale). The functions $\phi_A(v)$ and $\phi_Q(i)$ are interval scales (ordered metric scales) with an arbitrary origin (additive constant) and a common unit (scale factor).

The ADISOP model can further be strengthened to a model where the response category parameter also is additive to the item and subject parameter. The axiom W3 strengthens Co and extends cancellation from subjects and items to include subjects and instrumental variable (response category) and items and response variable.

Definition. A complete ADISOP (CADISOP) model is an ADISOP with axiom (W3) (and RS) replacing axiom Co:

Axiom W3. Weak instrumental variable independence holds if:

$F_{vi}(x) < F_{vi}(x')$ for some v and some i, then $F_{wj}(x) \leq F_{wj}(x')$ for all w and all j.

Axiom RS. Restricted solvability. Certain restrictions apply to the solution of stochastic dominances.

The weak instrumental variable independence axiom W3 is an independence axiom like W1 and W2 and makes the factor of the coding of the response variable X independent of the experimental factor of subjects and of the factor of items (for each value x of the instrumental variable the biorder of subjects and items is the same). It makes the coding of the instrumental variable another additive factor. Cancellation is no longer restricted to subjects and items but includes the response variable factor (an increase of the response category parameter by an amount c can be compensated by an equal increase in the subject or item parameter). Axiom RS grants that the system of equations and inequalities representing stochastic dominances has a solution under certain restrictions (e.g., if the CDF of subject v at item i and category x is between the CDFs of subjects u and w at item j and category x, then there is a subject s whose CDF at j and x' is equal to the CDF at (v, i, x); similarly for the item and category factors (Roberts, 1979: p. 218).

If the pair comparison system $\langle A \times Q, P\rangle$ is CADISOP then there exist scales ϕ_A on A, ϕ_Q on Q and ϕ_X on X such that for all $(v, i, x), (w, j, x') \in A \times Q \times X$

$$\phi_X(x) - (\phi_A(v) + \phi_Q(i)) \leq \phi_X(x') - (\phi_A(w) + \phi(j)) \Leftrightarrow F_{vi}(x) \leq F_{wj}(x').$$

The scales are interval scales with a common unit (scale factor). The 'system characteristic function'

$$F_{vi}(x) = F(\phi_X(x) - (\phi_A(v) + \phi_Q(i)))$$

is strictly isotonic in its argument (Scheiblechner, 1999).

The Integration of Linear Models for Item and Subject Parameters in Additive Models: Linear ISOP, ADISOP, and CADISOP Models

The ADISOP can be combined easily with an additive model for the item parameter:

$$\varphi_Q(i) = \sum_l a_{il}\eta_l$$

where a_{il} are known coefficients specifying the frequency or amount of 'basic components' l present in item i, and η_l are the (easiness, attractiveness) parameters of the basic components.

The matrix **A** with the coefficients a_{il} is termed the (item) model matrix. The estimation of the linear item model can easily be integrated into the algorithm for fitting an ADISOP model (Scheiblechner, 1999).

It is interesting to note that the coordinatewise partial order of items implied by the model matrix **A** can be tested in ISOP model with only ordinal scales for items (and subjects) available. The full linear model for items with interval estimates for the basic parameters, however, requires interval scales for items (and subjects) and thus an ADISOP. Thus in a model with latent scales and latent concatenations the question of additivity of item components cannot be separated completely form the question of additivity of item and subject parameters.

It is possible also to include an additive model for the subject parameter

$$\varphi_A = \mathbf{B}\cdot\delta$$

where φ_A is the column vector of subject parameters, **B** the (n, k) matrix of 'dosages' of (basic) treatments which were given to subjects and δ the column vector of 'gains' (increments of the subject parameter) caused by the treatments (the first column of **B** may be a column of 1s for an additive constant). The necessary supplements of the estimation algorithm are similar to the inclusion of the item model. Both extensions can be performed in a CADISOP model, of course.

The linear ADISOP/CADISOP models with the inclusion of linear models for items and/or subjects can be tested versus the respective unrestricted models by likelihood ratio tests.

Discussion and Future Directions

Probabilistic measurement models are known in psychophysics and utility theory, for choice behavior and pair comparisons, for decision making under uncertainty, and measurement of subjective probability. Not much attention is usually placed on estimation of parameters (probabilities and scale values) and statistical testing of fit (a rare but well-known and unsatisfactory (biased) example is Mosteller's test of fit for pair-comparison data). The probabilistic version of the additive conjoint measurement structure by Falmagne (1979) is a noteworthy psychophysical example for the statistical treatment of measurement models. Some statistical principles of estimation and testing could be borrowed and adapted from isotonic regression (Dykstra, 1983; Robertson et al., 1988). The tests concern stochastic (probabilistic) transitivity or consistency. The ISOP model is a weak stochastic transitivity model for a product structure $(A \times Q)$ and satisfies the statistical standards of probabilistic test theory. There are many statistical tests for various assumptions (axioms) in various parts of the data (see above, end of Introduction). The tests are based on generalizations of Goodman and Kruskal's index for ordinal association (1954, 1959, 1963, 1972). The U-model by Irtel and Schmalhofer (1982) is ISOP for dichotomous items and is its immediate precursor. The authors suggest an optimal contrast test for the bi-isotonic model (based on Robertson et al., 1988).

It is possible to specialize the ISOP model so as to pair comparison data (and to compare it with other probabilistic measurement models; Fishburn, 1973). It is possible also to generate probabilistic polynominal conjoint measurement structures (Roberts, 1979) by exactly the same steps as with ISOP structures (there is little use for those structures at present because no interesting empirical procedures for gathering corresponding data are known). Finally, it is possible to apply ISOP structures to geometrical measurement structures (multidimensional scaling, Kruskal, 1964a,b).

A permanent problem in psychological test theory is the modeling of the speed–accuracy trade-off for items where the speed and accuracy of the response are recorded at the same time. This problem can be attacked along the lines of isotonic probabilistic measurement structures whereby some interesting new problems arise.

Abstract

Textbooks are simultaneously surrogate curricula, cultural artifacts, and commercial products. As surrogate curricula, they define areas of study and normal pathways through these areas. As cultural artifacts they reveal, particularly through their latent or hidden curricula, particular societal values and norms. As commercial products, they reflect particular states of print production, distribution, and use. Textbooks evolved over the past 2000 years from original works and compendia of such works, to illustrated and tightly structured presentations of subject areas, accompanied quite often by pedagogical directions, assessment materials, and practice exercises. Across countries, subject areas, and grade levels, the position of textbooks in the educational process varies. Equally variable are the locus of control for textbook content and the nature of the groups that vie for this control. Due to the high demands that tertiary level textbooks make on capital and expertise, many developing countries, particularly in Africa, have become dependent upon the larger, wealthier countries for these products. The special role that textbooks play in education has been threatened in the past by programmed learning and computer-assisted instruction. In the future the threat will most likely derive from the digitized world of wireless communications and multimedia computers.

The textbook remains today what Altbach calls a 'virtual icon of education' (Altbach, 1991, p. 242), yet controversy surrounds nearly every aspect of its production, dissemination, and use, and its prospects for survival are uncertain in a high bandwidth, digitized, and wireless world. Textbooks in modern society function simultaneously as surrogate curricula, cultural artifacts, and commercial objects. Their development over the past two millennia has been driven by the evolution of formal schooling and of the printing arts, as wells as by the development, particularly since the start of the twentieth century, of educational psychology. Important differences in textbook form and use, and of the issues surrounding these areas, exist across the schooling levels – elementary, secondary, and tertiary; curricular areas; and countries. The form that textbooks will assume in the future is projected to change with the fuller integration of information and computer technologies in schooling.

Definition and Evolution

Definition

Textbook usually is interpreted in a general sense, referring to texts that are especially prepared for the study of a subject. The prototypic textbook has as its core a sequence of topics that are arranged to lead a student through a subject or course of study, accompanied on the periphery by occasional guiding statements, summaries, or the like, exercises for practice, questions for self-assessment, and assistance for the instructor. All textbooks possess the core element but differ in representation of the periphery. Primary level textbooks tend to possess all of the peripheral attributes; secondary level ones, most, and tertiary level ones, fewer. Nevertheless, all textbooks are viewed as surrogate curricula, defining a prescribed codification of knowledge.

Historical Development

Until at least the Enlightenment, textbooks for advanced study were either original works, such as the grammars of Donatus and Pricisian, Boethius's *Geometry*, and Ptolemy's *Mechanisms of the Heavens*, or abridged compendiums of these works, such as Martinus Capella's *The Marriage of Mercury and Philology* (Cubberley, 1920). For children, specially developed materials originate with the *Orbis Pictus* of Comenius (1658/1887), which was the first illustrated schoolbook published for introductory learning. By the end of the seventeenth century primers for teaching reading were published in Europe with the alphabet, lists of syllables and words, as well as religious material: the Lord's Prayer, the Creed, and so on. From the influence of Rousseau and Pestalozzi came, by the second decade of the nineteenth century, carefully sequenced materials for learning, along with occasional suggestions for the instructor. With the adoption of tax supported schooling, particularly in Europe and North America, both the market and the need for textbooks expanded dramatically, leading to changes in both size and content. Coincidentally, improvements in printing technology and paper making throughout the nineteenth century were also reflected in textbooks. With the rise in educational psychology, beginning at the end of the nineteenth century, instructional approaches became more differentiated and more scripted, leading by the post-World War II period, to separate teacher manuals to accompany many elementary and secondary level textbooks.

Surrogate Curriculum

According to Altbach and Kelly (1988, p. 3), '(Textbooks) constitute the base of school knowledge, particularly in third world countries where there is a chronic shortage of qualified teachers.' But even in industrialized countries textbooks are the primary codification of school knowledge and the principal guide for teachers. Teachers at the elementary levels, who are responsible for teaching a broad curriculum in self-contained classrooms, choose out of necessity to use textbooks, along with workbooks and teacher guides. At higher levels of schooling the textbook is as much a prop for students, a *vade mecum* for a course, as it is a guide for the instructor.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.95064-5

Grade Level Differences

Although textbooks are used at all levels of education and in all subjects, their importance varies not only across countries but also across grade levels and curricular areas. At the primary levels their use is limited primarily to literacy, at least until the students, on average, can read well enough to gain meaning from other content area texts. In many school systems language arts and mathematics texts may be the only ones commonly used prior to the fourth or fifth year of schooling. Then, through the first years of graduate school, textbooks tend to be the basis of instruction for most subject areas.

Subject Area Differences

Thomas Kuhn has pointed out in *The Structure of Scientific Revolutions* that at the college level textbook use varies dramatically by field of study. Music, the graphic arts, and literature typically are taught through direct exposure of the student to artists' works, textbooks playing only a secondary role. In history, philosophy, and the social sciences, textbooks have a more significant role, but students usually are also assigned readings from the classics and from contemporary research reports. In contrast, the natural sciences are taught almost exclusively from textbooks (Kuhn, 1970). Within the natural sciences, textbooks are rewritten after each paradigm shift (or 'revolution,' in Kuhn's terms), with the revolution obscured and the past reinterpreted to show only its connection to the issues of the new paradigm.

Use of Textbooks by Teachers

How teachers use textbooks is a matter of concern for educational administrators. In developing countries where teachers may not be well trained, close adherence to the sequence and directions of the textbook is desired. In other countries, reliance upon textbooks, particularly at the primary levels, is not viewed positively. Studies of teaching practices, however, have tended to show that high percentages of elementary teachers do use textbooks as their primary guide for instruction (e.g., Shaver et al., 1979; Weiss, 1987). But other studies have shown that teachers, in general, do not follow their textbooks slavishly (e.g., Stodolsky, 1989).

Control of Textbook Content

In most countries a central ministry of education determines the general content of textbooks but the actually writing of the texts may be performed by persons outside the ministry, as in Russia, or within the ministry, as in Singapore. In the US, Canada, and Germany control over textbook content is vested at a provincial or state level, although the actual texts are produced by the private sector. In many developing countries, where indigenous textbook industries generally are not yet developed, multinational textbook companies exercise some control over content. French produced textbooks, for example, are used in many West African secondary schools (e.g., Togo); some of these texts portray sex roles and other culturally sensitive matters that are alien to West African cultures (Biraimah, 1988).

Imported Textbooks

At a postsecondary level and especially in technical subjects, textbooks are relatively expensive to produce, due to the cost of illustrations, complex diagrams, formulas, and the like. Many countries, including the smaller industrialized ones such as The Netherlands, Finland, and Luxembourg, must import textbooks for these levels, and the majority of the these texts are written in English. A further factor that affects the content of textbooks worldwide, but particularly at a secondary and tertiary level, is that a small number of highly industrialized countries dominate knowledge production and dissemination. Countries like the US invest large amounts of money in all fields of research and development, including educational research, and tend, therefore, to set many of the tertiary level standards worldwide for curriculum and assessment. Through academic institutions, research laboratories, libraries, and professional journals, countries like Britain, Germany, and the US exert both direct and indirect influence over textbooks in most of the rest of the world. That this knowledge is shared freely is offset partially by the reduction in cultural autonomy that results.

International Concerns over Content

Even within a world that recognizes, at least in principle, the right of each country to design and teach its own curriculum, cross-national conflicts over curriculum content have occurred. One example is the concern expressed by a number of countries to specific national treatments of twentieth-century history and particularly of World War II and the Holocaust. In 1982 The People's Republic of China and South Korea protested changes in Japanese history books that removed references to the Japanese massacre in Nanking and watered down the language previously used to describe other Japanese behavior toward conquered territories (Ketcham, 1986). More recently, an Austrian publisher of a high school history series was forced, through pressure from other countries, to stop referring to Nazi concentration camps as 'punishment camps.' History texts in the US have been attacked for over a half century for lack of fairness and objectivity in describing wars (Walworth, 1938), for being bland and condescending (Sewall, 1987), and for failing to attribute blame to individuals (FitzGerald, 1979). Similarly, science texts have been criticized for their handling of evolution (Skoog, 1984).

Cultural Artifact

The Latent Curriculum

The table of contents and index of a typical textbook define, to a large degree, the manifest curriculum offered by the text. But on top of this curriculum are a secondary set of messages, reflected by commission and omission, that constitute the latent or hidden curriculum (Cronbach, 1955). In part, this is what Williams calls the selective tradition of society (Williams, 1980). A mathematics textbook that constructs its word problems around interests of a consumer society – goods to be purchased, interest on loans, fees paid for services – conveys a different message from one that presents the same mathematical challenges built around revolutionary themes – distribution of land to the poor, triumph in sports over capitalistic societies, and so on. In China, for

example, mathematics textbooks during the Cultural Revolution conformed to the prevailing ideology; with a shift in politics, mathematics textbooks by 1980 were stripped of all praise for the Gang of Four and their policies (Kwong, 1988).

Class Structure

Texts for teaching reading have been studied worldwide for different aspects of their latent curricula, including gender roles (e.g., Lorimer and Long, 1979–1980; Zimet, 1972; Biraimah, 1988), need for achievement (e.g., McClelland 1961), moral/ethical values (e.g., de Charms and Moeller, 1962), and sociocultural ideologies (e.g., Ahier, 1988; Apple and Christian-Smith, 1991; Luke 1988). Drawing on Paulo Freire's claim that pedagogy for literacy, by definition, requires an educational ideology, some of these latter authors argue that in countries such as Britain, the US, and Canada, literacy textbooks are as much concerned with maintaining class structures and political hierarchies as they are with imparting reading and writing. Although there is a surface validity to these claims, as demonstrated particularly by textbooks from the 1950s and 1960s, they are difficult hypotheses to test on modern textbooks in industrialized countries, given the pressures on publishers to produce textbooks that are unbiased toward any sex, race/ethnicity, age, country of origin, or political belief. Texts today could be attacked as much for failing to promote cultural continuity as for over-representing any particular class or belief in society.

Commercial Object

In almost every country that has formal schooling, textbooks have some relationship to the commercial sector. In Singapore, for example, textbooks are designed and written by a Ministry of Education, but copublished with private sector firms. In the USSR, prior to its breakup, the Ministry of Education or a State Committee for Public Education designed the content of textbooks but authors were selected through public competitions and paid royalties for their efforts, which were published by state controlled printing houses. In Mexico, where textbooks have been provided free to the six grades of public and private elementary school, government support has been provided to develop what World Bank researchers have called 'the most dynamic private sector publishing industry in Latin America' (Neumann and Cunningham, 1982).

Concentrations of Expertise and Production Capacity

Textbook publishing and marketing require expertise in subject matter and pedagogy, along with capital, production and distribution capacity, and access to paper. These resources are found primarily in the major metropolitan centers of North America, Asia, and Europe, and are increasingly being dominated by the larger European conglomerates – Pergamon and Pearson in the UK, Bertelsmann in Germany, and Hachette in France. Even in the US, few major textbook publishing houses have remained independent. The rest of the world lies in the periphery of textbook publishing, even though many other large countries such as India, China, Mexico, and Egypt produce many if not most of their own textbooks and the latter two export regionally to smaller developing countries (Altbach, 1991).

Physical Characteristics

The appearance of textbooks – the quality of paper, typography, illustrations, bindings, and cover stock – are a function of printing technology, different national economies, grade level, and national (or regional/local) educational policies, such as the adoption cycle. In all school systems primary level textbooks usually are done on the cheapest paper, often with paper covers and limited use of color for illustrations. Russia textbooks, which the former Soviet government subsidized, were produced to last 2–3 years and were done with cheap paper, cover stock, and bindings. In contrast, textbooks in the US are produced to last 5–7 years and due to market factors have far more expensive components. But they also cost almost 10 times as much as their Russian counterparts (Mehlinger, 1991).

Authorship

Authors of secondary and tertiary textbooks generally write the works that bear their names. At the elementary level, on the other hand, writing houses or other anonymous writers often do the majority of the development. The authors usually are involved in planning and review, and may even draft a few model lessons, but their main function is to impart validity to the resulting product, through their professional reputations, affiliations, or their race/ethnicity, age, or sex. In the US, most elementary reading textbooks in the eighteenth and nineteenth centuries were authored by single individuals, with a few having two authors, or (rarely) three. By the early part of the twentieth century, most readers had two or three authors, by the 1950s, four, and by the 1970s, as many as eight authors and instructional consultants (Woodward, 1986).

Marketing and Adoption

In many countries, including some with national ministries of education, textbooks compete in a partially open marketplace. The selection of textbooks for schools, however, is often enshrouded in a complexity of national, regional, and local politics. In the US, where local control of schools and lay control of the school curriculum are fundamental tenets of the educational process, school board prerogatives for textbook selection often clash with particular citizen interests as well as with state and national politics. State-wide adoption practices, initiated originally for both economic and political reasons, have led to several heavily populated states (e.g., Texas, California) exerting unwarranted influence over the entire elementary and high school textbook trade.

The Future of Textbooks

In a science fiction classic entitled *A Round Trip to the Year 2000 or a Flight through Time*, written by Cook (1903), news and-novels in the year 2000 are no longer printed. Instead central 'bureaus' transmit voice recordings upon request from phonographic records. However, textbooks still exist and

specific mention is made of a 'text-book on Applied Psychology which has a place in every school in the nation' (Cook, 1903/1974, p. 109). Whether the projected survival of textbooks was considered as a positive or negative factor by the author is not known; however, while daily newspaper reading has declined steadily since the early 1950s and the novel has been declared dead at various times over the past decades, textbooks have continued to thrive at all levels of education and in all countries where formal education exists.

In the 1960s the main threat to the existing form of textbooks was the programmed textbook, a dull, tedious approach to sequencing subject matter in baby-sized bites, based on the behavioral conditioning studies that the psychologist B. F. Skinner performed with pigeons and rats (Reid, 1969). In the 1980s computer-assisted instruction was offered as a hightech alternative to textbooks and to teacher directed instruction, with the promise that each student could progress at his or her own pace – a goal that was seldom challenged by educators. Today the World Wide Web (WWW), hypertext, and inexpensive, book-sized computers that can display texts on high quality displays, are the assumed replacements.

For the developing world, which is still struggling to recruit and train sufficient numbers of teachers and to provide adequate buildings for schooling, the provision of textbooks written in the national languages and appropriate for their cultures remains a challenge. Similarly, smaller industrialized countries would like to find inexpensive approaches for producing or adapting tertiary textbooks to their languages rather than importing them. Finally, for the historian, the preservation of textbooks remains an issue. Few, if any major research libraries are willing to invest resources in preserving and cataloging textbooks, particularly elementary and secondary ones. Fortunately, a number of newer research centers and projects for the study of textbooks have been funded, including the Japan Textbook Research Center, The Teaching Resources and Textbook Research Unit in the Faculty of Education at the University of Sydney, Australia, the UNESCO International Textbook Research Network (in cooperation with the Georg Eckert Institute in Germany), and the Textbook Colloquium in the Open University Faculty of Arts in the UK.

This article is a revision of the previous edition article by M. Monmonier, volume 23, pp. 15636–15641, © 2001, Elsevier Ltd.

Abstract

Thematic maps represent information about a specific topic or about the relationship between topics. Producing effective thematic maps relies on selecting an appropriate base map and an understanding of the nature of the data being mapped. Once the representation method is selected, the individual symbols need to be designed, using variations in the visual or graphic variables. Having introduced these concepts, I go on to discuss basic strategies for representing data using point, line, and area symbols.

Introduction

Maps can be divided into three groups: topographic or reference maps; special purpose maps; and special topic or thematic maps. These three groups are closely related to three major types of map-use tasks (Keates, 1996). Topographic or reference maps are used to find out information such as the location of a place and, in theory at least, represent a balanced view of the physical and cultural landscape, including coastlines, roads, rivers, settlements, boundaries, etc. Special purpose maps are mostly associated with wayfinding, some being associated with trained users, such as hydrographic and aeronautical charts, and others with broader user groups, such as road and tourist maps. Sometimes referred to as 'special topic' maps, as the name implies, thematic maps emphasize a topic or theme, such as soils or population, and are used where there is a desire to learn about a particular topic. The topic can be relatively broad, such as global population distribution, or very narrowly focused, as for a map showing infant mortality for a specific year by districts within a city. It is also possible to show the relationship between phenomena, for example, a map showing how educational attainment and income levels compare and relate across a region. Comparatively rare at the outset of the nineteenth century, thematic maps as a group have become more numerous, varied, and intellectually richer as data have become available and representation techniques have developed (Robinson, 1982), and the current popularity of map 'mash-ups' on the World Wide Web has brought them to a much wider audience. This article examines the distinctive elements of thematic maps, including principal strategies and pitfalls.

Elements of Thematic Mapping

Thematic maps have two main components: a base map and the thematic overlay. Typically the base information comes from topographic or general purpose mapping, most likely today in the form of a cartographic database. The special topic information comes from a much wider range of sources. Specific field surveys may have been carried out on features such as geology, or vegetation, or nonmap sources such as government census, and other databases of attribute information that have some spatial reference may be used. In terms of map design, two approaches can be taken. In some cases, an integrated approach is used where reference and topic information is considered together and specific symbols chosen to represent each feature appropriately. Alternatively, in many cases, the base map is used with little or no modification, or perhaps all just reduced to gray, and the special topic information is overlaid on this base, typically using stronger colors. Many examples of the latter approach can be seen today using Google Maps as the base, overlaid by markers of thematic information. Regardless of which approach is taken, the aim of map design is to create a visual hierarchy of information, with the base information less visually prominent than the thematic component, so that the user may focus on the specific distribution or relationship, as shown in Figure 1.

An Appropriate Map Projection is Essential

Because the Earth is spherical and most maps are flat, the base map distorts the geometry of boundaries and other reference features (Maling, 1992). The amount of distortion depends in a large measure on the map's scale, defined as the ratio of distance on the map to distance on the Earth. On a 'large-scale' map covering a small area, such as a neighborhood or archaeological excavation, distortion will be minimal. By contrast, a 'small-scale' map covering a large area, such as a continent, hemisphere, or the entire World, must distort large shapes, distances, and directions, and may also distort angles and areas. By selecting an appropriate projection, the map author can avoid distortions that are likely to mislead readers. At larger scale, certainly at 1:250 000 scale and larger, it is likely that national topographic mapping will be used as the base, without any change of projection. At smaller scales, for most purposes in thematic mapping, an 'equivalent' or equal-area projection should be selected, but frequently authors simply use what is available, which can lead to concerns about fair representation of information. Often a distinct disadvantage of using readily available Web mapping (such as Google Maps or Bing Maps) as a basis for thematic maps is that the projections used for display are not equal area.

Figure 1 A thematic map consists of a base map and a thematic overlay.

Geocoding

In order to map data, there must be a way to plot the data on a base map. Where data have been expressly collected for mapping, this is likely to be straightforward. In other cases the map maker may have to create a link between the topic information and the base map. For census and many other socioeconomic data sets, the data have been gathered based on some form of political or administrative units, such as countries, states, wards, etc., depending on the scale of the data. As long as there is a field (attribute) in the data set that matches one in an appropriate boundary file, then the geocoding process is simply a matter of linking the attribute data to the spatial data (Goldberg, 2008). However, often there can be imprecise definitions of location in thematic data sets which may require manual effort to resolve any nonmatched data. It is also quite likely that boundaries will have altered over time, so care is required to ensure an appropriate set of boundaries is used. For some data sets it may be possible to use postal or zip codes to relate the topic information to a spatial data set. The Internet has greatly increased the availability of suitable base data sets, but beyond national- or state-level boundaries it may be difficult to find an appropriate data set for many parts of the world, and often there are quite high prices for detailed boundary data.

Understanding the Data to be Mapped

The data will likely require some processing and/or classification in order to be in a suitable form for mapping. The author must have an understanding of the nature of the data so that appropriate representation methods and symbols can be specified. First to consider is the spatial nature of the phenomena. Generally speaking, we can identify four types of spatial distribution: phenomena can be found a specific point location, or at least a location considered to be a point at the scale of mapping (such as a city on a very small-scale map); they can be distributed along lines; they can fill an area defined by some form of boundaries; or they can vary continuously over the surface. In most cases, the spatial data we have about the phenomena will be points, lines, or area boundaries. The relationship between the phenomena and the spatial data may not always be simple. For example, people live at specific locations, but typically the data we have is collected for enumeration areas, often to protect individual anonymity. So, although we know the data are about a point phenomenon, what we have for mapping relates to bounded areas. Similarly, it is not possible to collect data for every possible point over a surface, so data may be a sample of points, or lines on the surface. This relationship between the phenomenon and the spatial data is often an indirect one as frequently we are dealing with processed data or secondary sources. In choosing an appropriate mapping technique, it is important to think about what we are trying to map, not just the data we have.

The second aspect to consider is the nature of the attribute we are mapping. Often this is discussed in terms of the 'level of measurement' of the attribute. Many texts recognize four levels of measurement: nominal, ordinal, interval, and ratio. Nominal or qualitative data are where the distinction between members of the data set is by some form of naming or categorization; such as crop type or ethnic origin. Ordinal data are where there is some ordering or ranking of the data, such as, for settlements: National Capital, State Capital, County town, etc. Interval and ratio measurements are both quantitative and are often considered together, the key difference being the origin of the scale and how appropriate various mathematical operators are on the scale. This simple classification is satisfactory in many cases, but Chrisman (2002) and Forrest (1999) considerably extend the classification to help determine appropriate operations on and representations of the data. For example, it is frequently necessary to distinguish between count data, where the total number present in an area is mapped, and intensity data where the relative density or proportion of a phenomenon is mapped, even though both types are numerical and measured on a ratio measurement scale.

Issues relating to this difference between count data and intensity data are well illustrated by Figure 2. All three maps essentially illustrate the same phenomena, infant mortality in the eastern half of the United States. At the left, proportional circles describe differences in the number of infant deaths; a bigger circle unambiguously representing more deaths for that state than a smaller circle. In the center, a gray-tone treatment of the same data yields a potentially misleading map with dark symbols for states with relatively large numbers of deaths and comparatively light shades for states with fewer deaths. The dark tones suggest a health crisis in New York, Florida, and other relatively populous states and comparatively benign conditions in less-populous states such as Alabama and Mississippi. By contrast, the gray tones of the right-hand map offer a far more realistic portrait of the geographic variations in infant mortality which adjusts infant deaths for the number of live births. This recognizes that the size and population of the state will have an impact on our perception of the data. By relating the infant deaths to a more meaningful variable and mapping the proportion, we are in effect normalizing the data and removing the artifact of variable size states. If all states were the same size and population evenly distributed, we would not have to worry about such issues, but this is rarely the case.

Once the relationship among phenomenon, spatial data, and attribute measurement is understood, the map maker can choose an appropriate representation method. In many cases there is little choice, but, as we have seen in the example above, in some cases there may be several options (see Section 'Principle Cartographic Strategies').

The Visual or Graphic Variables

Having chosen the representation method, the individual symbols representing each class of information need to be designed or chosen. These symbols are the language of the map – the way the map maker communicates information to the reader.

Jacques Bertin (1983), a French semiologist who proposed a formal theory of graphic language, recognized eight visual variables: the two variables of location in the visual field (x- and y-coordinates) and six 'retinal' variables portraying a feature's character. The six retinal variables described by Bertin are size, shape, orientation, texture, color hue, and color lightness. Other cartographers have since developed Bertin's theory to include additional variables, such as the generally recognized third variable of color – color saturation, pattern, focus (relating to the sharpness of the symbol), and others (e.g., MacEachren, 1995). To some extent, how much Bertin's original set of variables should be extended depends on the interpretation of the variables. For example, some authors do not consider shape to be a possible variable for area symbols as the external shape of the area cannot normally change, preferring to introduce the variable 'pattern' for variation in the shape of the component elements covering the area, whereas others accept that the use of 'shape' refers directly to such components (as Bertin did), making 'pattern' unnecessary.

More recently, consideration has been given to variables that are possible on interactive computer displays, such as motion, duration, and synchronization which are not possible on paper maps (MacEachren, 1995; Slocum et al., 2009). While such dynamic variables must be viewed over time, their intention is to represent some other variable, not temporal change.

Table 1 summarizes the suitability of Bertin's six retinal variables for representing attributes with different levels of measurement. Generally speaking, it becomes obvious that those variables suitable for representing qualitative data are less suitable for representing quantitative data, and vice versa. If even such basic guidelines were followed by map authors, we would see far fewer maps representing data in inappropriate ways.

Figure 2 Comparative treatment of count (left and center) and intensity (right) data with symbols varying in size (left) and colour lightness (centre and right). Misuse of intensity symbols for count data on the center map yields a misleading pattern.

Table 1 Use of visual variables for different types of attribute measurement

Measurement	*Nominal*	*Ordinal*	*Interval/Ratio*
Visual variable			
Size	Poor	Usable	Extensive use
Shape	Extensive use	Some use, generally combined with size	Poor
Orientation	Good	Poor	Poor
Texture	Some use	Usable	Limited use
Color hue	Extensive use	Some use	Limited, but can use spectral ordering
Color lightness	Poor	Usable	Extensive use

While Bertin's visual variables have had significant influence on cartographic textbooks, further aspects of his theories of graphics are often overlooked although they do provide a key to what we are often trying to achieve with our symbols. Bertin also discussed the perception of the image and identified four possibilities. In *associative* perception, the impression is of similarity; we can see there are differences, but association between symbols is emphasized by having relatively low contrast between them. On the other hand, with *selective* perception we immediately separate the visual field into two (or more) groups, but none is perceived as more important than the other; typically this process involves greater contrast. *Ordered* perception is where we can see a clear ranking, in that one feature is seen as more important than another. Finally *quantitative* perception is where we get some impression of the relative numeric value of the phenomena. Figure 3 illustrates these four properties with the examples of point symbols, but this could also be done for lines or areas and use different graphic variables.

Principle Cartographic Strategies

Although the range of possible map topics is limitless and interactive graphics has greatly expanded the possible methods for visualizing geospatial data, for static mapping, an examination of printed atlases and cartographic textbooks will confirm that relatively few commonly used cartographic representation methods are in use. These methods (sometimes called different types of maps, rather than methods) are sufficient to portray most combinations of phenomena and mappable data. Although there are different ways to classify them, they will be treated here by way of the point, line, area, and surface representation methods. These representation methods are summarized in Figure 4.

Figure 3 Bertin's classification of image perception: (a) associative, (b) selective, (c) ordered, (d) quantitative.

Representations Using Point Symbols

Seemingly a simple method, the dot distribution method represents information by a series of small dots, all of the same size and shape. It is possible, but uncommon for each dot to represent one individual; generally each dot represents a number of occurrences of the phenomena. For example, a dot may represent 100 people. Three issues need to be resolved: what is the ratio of features per dot, what size should the dots be, and where should they be placed. The first and second are interrelated. The dots need to be large enough for isolated dots to be noticed, but not too large, because it is the distribution pattern that is important, not the individual dot. Ideally in the densest areas dots should coalesce to become almost solid. Where to place the dots is often the biggest challenge. Although many computer systems can produce 'dot maps,' generally they use a random number generator to scatter dots within an enumeration area, which is not effective. Further information, such as a topographic map, is required to decide where the phenomenon most likely occurs. A good dot map is an excellent way of representing distributions, but the effort required to logically place the dots limits their use.

A more common way of representing quantitative data by point symbols is the proportional or graduated symbol. Here the size of the symbol varies in relation to the value of the topic, as shown on the left in Figure 2. With proportional symbols, this variation in size is in direct proportion to the value, such as the area of a circle or square increasing in direct relation to the value. Unfortunately, where there is a great data range, it can be impossible to create a scale where the smallest symbols are visible, but the largest are not too big to dominate the map. The solution is to divide the data into classes (much like choropleth maps) and have a fixed size symbols for each class, creating a set of graduated symbols. The most common symbol is the circle, which has a number of advantages, but other shapes are also used. Our perception of the relative size of squares is better than circles, so their use should be

Figure 4 Basic cartographic representation methods (after Forrest, D., 1999. Geographic Information: its nature, classification and cartographic representation. Cartographica 36 (2), 31–53.).

more popular than it is. There is some use of pictographic symbols, particularly in journalistic maps, but our ability to estimate the relative value of more complex shapes is poor, so they are probably best avoided.

Where the data for the location can be broken down into components, a number of options are possible, such as pie charts, or various other graphic devices located at points. These can either be fixed in size, with the focus being on the relative proportions of the components, or varied in size like proportional and graduated symbols to convey both the overall total distribution and the breakdown of components.

For nonnumerical data, we simply show each category by varying the shape and/or hue of the symbol. The key design aspect here is to make the symbols appear different, but equivalent. When appropriate, pictographic symbols can be exploited here as the user can understand the meaning of the symbols without referring to the legend.

Representations Using Line Symbols

Boundaries are a common feature represented by lines. Generally the data about these are hierarchical, so the symbols chosen should emphasize the rank of the individual boundary. This could be done by simply varying the thickness of the lines, but most often a combination of thickness and line pattern (dashes) is used, with shorter, thinner dashes for lower-ranked boundaries.

Representing quantities by line symbols can either involve a network of lines or flow lines simply connecting pairs of points or areas. This tends to get little coverage in cartographic texts, perhaps because, in the writer's experience, they are often challenging to both design and produce. The obvious graphic solution is to vary the width of the lines in proportion to the variable being mapped, but there is a limit to the range of data that can be treated in this manner. One problem is that if two lines have the same value, but differ in length, the longer one may give the impression of having greater value. With the flow type of map, crossing lines pose further problems for both design and perception.

Another way of representing route information is a linear cartogram, the most famous example being the London Underground map, but a similar style has been used for many metropolitan subway systems, rail and bus networks. Space is distorted for clarity and simplicity purposes, often with the angle of lines limited to a few directions (usually 6 or 8). Scale is varied to allow space in more detailed areas, often city centers, where routes converge and stops are closer. Scale can be reduced where there is less to show, such as in the outer suburbs. Typically each route is shown by a different color. Often there is no other information, but major geographical features, such as the River Thames in London, may be included in simplified form.

Representations Using Area Symbols

Many maps represent qualitative data about areas, such as those about geology, soils, and vegetation. There is no generally accepted term for this form of cartographic representation. In some U.K. textbooks, the term 'chorochromatic' has been used and some North American texts use terms such as 'color-patch' or 'mosaic' maps, both of which adequately describe their appearance. Unfortunately some use the term 'choropleth map' (see below), but should only be applied to quantitative maps. At larger scales, the design of this type of mapping is often demanding due to the large number of classes and subclasses that can be present. Using many classes requires imaginative use of the graphic variables to ensure that a balanced representation is achieved where no class should appear more important than another. With a classification hierarchy, a major concern is to ensure that subclasses are clearly associated with others within the same overall category and have a greater difference to those in other categories. Often this is solved by using a main color (hue) to distinguish the top-level categories and use of patterns or texture to differentiate subclasses.

Probably one of the most widely used techniques for thematic mapping is the choropleth map, as shown on the right of Figure 2. This represents quantitative data for areas, usually some form of administrative unit, such as country, state, wards, census tract, or some other areal unit. They are popular partly because there are enormous amounts of numerical data available for areal units and, assuming the boundary data are available, they are easy to produce using desktop mapping systems and Geographical Information System (GIS). This ease of production has also led to great misuse, typically using data that are affected by the variation in zone sizes as discussed above in terms of representation, but also by poor selection of the area symbols. The typical approach is to represent the data values by light-to-dark series of ordered gray tones or varying the lightness of a single hue, such as shades of green from light to dark. With a single hue, the number of classes that the user can easily identify is generally four or five; if more classes are required, then a part spectral scheme can be adopted, perhaps going from yellow, through oranges, to reds. For showing data such as rates of change where there can be both positive and negative values, two contrasting hues can be used, such as red and blue, becoming darker as the value increases in each direction. Sometimes a neutral color can separate the two scales, representing no, or minimal, change. Such a scheme can also be applied to emphasize variation from the mean, such as divorce rates, where the regional average could be used as the dividing point. In recent times, a 'traffic light' color scheme has become popular, using green for good/above average, yellow for neutral, and red for poor/below average, particularly when applied to performance data, or business data such as sales figures. An excellent resource for investigating color choices for choropleth maps (and some other types) is the ColorBrewer Web site (Brewer and Harrower, 2009).

Apart from the choice of color scheme, the two key decisions are the number of classes to depict and the choice of class intervals. The fewer the classes the more generalized the representation; too many classes and the user starts to have some difficulty in distinguishing among them. It is also possible, but less common, to produce choropleth maps without classes (see Kennedy, 1994). Because different classifications of the data can produce radically different spatial patterns, the efficiency and effectiveness of a choropleth map depends heavily on its categories (Evans, 1997). Common approaches include equal intervals, where the data range is divided equally, and quantiles, where the same number of zones is included in each class. The choice would not be difficult if data were evenly or normally distributed, but often it is not, and highly skewed data sets present significant difficulties in selection of appropriate classes. Mechanical selection of classes will often result in rather meaningless class boundaries. A wise practice, often ignored, is the use of inherently meaningful category breaks, such as zero on a map of migration rates, or the national mean on a map of per capita income (Monmonier, 1993).

Figure 5 Area cartograms adjust the size of areal units according to a transforming variable such as population. Contiguous cartograms (left) may distort shape severely, whereas non-contiguous solutions (right) preserve shape but lose contiguity.

A major disadvantage of choropleth maps is that the boundaries often bear no relation to the actual spatial distribution of the phenomenon. Dasymetric maps appear graphically similar to choropleth maps, in that the data are represented in a similar manner, but in this case the boundaries are drawn to reflect uniform areas in the distribution of the specific phenomenon. Clearly, producing such boundaries requires additional information and effort compared to the choropleth map, which goes a long way to explain their limited use, especially when maps of many variables are to be produced.

On an 'area cartogram,' the size of the areal units being mapped varies according to population or some other transforming variable. As Figure 5 illustrates, noncontiguous cartograms sacrifice contiguity for shape whereas contiguous area cartograms may require severe distortions of shape in order to retain contiguity. Unless the reader has a good grasp of the original geography, the distorted shapes may make the size differences meaningless. This can effectively be countered by showing both a geographically correct map (typically choropleth) adjacent to the cartogram, so that an easy comparison can be made. Assuming that the reader appreciates the distortion in geography, cartograms make a dramatic demonstration of disparities in aspects such as population, wealth, education, or military spending. An isodemographic map – a population-based area cartogram – can also provide a useful base map for representation of other socioeconomic data, election outcomes, and public health (Dorling, 1994). Adjusting the base map for population in this way diminishes the exaggerated impact of large areas with small populations and ensures small, densely populated areas are visible. The availability of software to generate effective contiguous cartograms has significantly increased their use.

Representations of Continually Varying Surfaces

Sometimes referred to as contour maps, isarithmic maps refer to maps that represent continuously varying quantities over the surface by lines of equal values. Strictly, the term contour should be used only when the variable mapped is terrain height. Common terms are used for some variables, such as isobars for pressure. Terrain contour maps typically use an equal vertical interval between contour lines. In this case, the user can appreciate slopes by variations in the spacing of the contours. In many thematic mapping situations, nonequal intervals are used, so the nature of the 'surface' can be harder to visualize. This approach is often adopted because the data values are highly skewed or because the map maker wants to emphasize some particular values.

An extension of the isarithmic map is to apply a scale of colors to the zones between isarithms. The choice of colors is similar to that for choropleth maps, but more classes, with smaller color difference is successful here due to the nested nature of adjacent zones. GIS and surface modeling software make extensive use of a chromatic scale with large numbers of classes. Generally the data range is automatically divided by the number of steps in the scale, often resulting in unwieldy values in the legend, rather than selecting a simpler, more rounded interval.

Like the surface being represented, there is some value in adopting a representation method that also varies continuously. In terrain mapping, hill shading uses a continuously varying gray tone to represent relief. In its simplest form, the steeper the slope the darker the shading. To give a better impression of the three-dimensional nature of relief, such shading is often modified to have an assumed light source coming from the top left of the map, but this is probably not appropriate for other surfaces.

Other techniques of representing continuously varying surfaces depend on a nonorthogonal view of the mapped area. This includes fishnet plots and fully rendered block diagrams.

Conclusions

The power of the computer and the development of GIS and scientific visualization software have lead to a significant development of representation methods in recent years. Some of these possibilities have been known for a long time but have been too costly or impractical to carry out manually. Many of the newer methods rely heavily on interactivity and so are beyond the scope of this article. With modern systems, there is more scope to experiment with representation, as a change of color, or even representation method can happen in an instant with the click of a button. Despite these advances, the basic principles of thematic mapping, understanding data to be mapped, and proper use of the visual variables remain as important as ever.

Theory of Mind During Infancy and Early Childhood Across Cultures, Development of

Beate Sodian and Susanne Kristen, Ludwig-Maximilians-University Munich, Munich, Germany

Abstract

This article presents a summary of Theory of Mind (ToM) development across cultures. It presents cross-linguistic and cross-cultural research on implicit and explicit ToM skills, ranging from ToM in infancy through children's emerging mental state talk to children's explicit comprehension that others might hold false beliefs and that their actions are guided by them. It is argued that more research is needed, especially research contrasting the multiple facets (parental practices, beliefs, language) through which culture might contribute to ToM development. Finally, cultural effects on the relations between ToM and its developmental factors are discussed.

Theory of Mind

A Theory of Mind (ToM) is the ability to attribute mental states to oneself and others and to use these attributions for the prediction and explanation of action. ToM is sometimes called a belief–desire psychology, since the attribution of beliefs and desires is central to our commonsense mentalism. Children acquire a ToM in two steps: By the age of 2.5 to 3 years, they understand the subjectivity of desires and predict an agent's action based on their desires, and by the age of about 4 years, they understand that beliefs may differ from reality and that agents' beliefs, rather than the state of reality, will determine their actions (Perner, 1991). For example, when shown a typical container for sweets (a Smarties tube), and informed about its rather unusual content (a pencil), 4-year-olds will predict that their friend, who has not been able to look into the container, will believe that there are Smarties in the container, whereas 3-year-olds will typically answer that an uninformed other will say that there is a pencil in the container. The concept of belief is crucial to an understanding of the mind, since it entails the distinction between reality and a mental representation of reality. Since the first systematic investigation by Wimmer and Perner (1983), a large body of evidence on the development of false-belief understanding in preschoolers has been gathered, mostly using story format tasks such as the location-change task in which a story figure (Maxi) places an object (chocolate) in location A, then leaves; during his absence another story figure (Mother) transfers the object from A to B; then Maxi returns and looks for the chocolate; the child is asked the test question: "Where will Maxi look for the chocolate?" or "Where does Maxi think the chocolate is?" In a meta-analysis of more than 500 studies of false-belief understanding by Wellman et al. (2001), a robust developmental trend was observed, across tasks and situational factors, between 3 and 5 years of age; under some task conditions, improved performance was observed in 3-year-olds, but a marked age-trend persisted. Children with autism show a severe deficit in false-belief tasks and acquire a ToM only with a gross delay and persisting deficiencies even in adulthood (Hill and Frith, 2003). Taken together, these findings indicate a conceptual deficit in typically developing 3-year-olds and in children with autism. Conceptual coherence in ToM development is indicated by close interrelations between a whole set of conceptual distinctions (e.g., appearance and reality, different visual perspectives on the same entity) and causal relations (e.g., seeing-knowing) that are acquired around the same age as the concept of belief and by the findings of training interventions, indicating transfer effects (Slaughter and Gopnik, 1996). ToM development in preschool age is closely related to language acquisition and to the development of executive functions. However, 3-year-olds' difficulty with ToM tasks cannot be accounted for by the linguistic and executive demands of the tasks (Perner et al., 2002).

Implicit ToM in Infancy

An implicit understanding of false belief precedes a full or explicit one. In early studies (Clements and Perner, 1994), young 3-year-olds were shown to take an agent's false belief into account in their anticipatory looking, while they failed when asked for an explicit judgment of the agent's belief or a prediction of his action. More recently, rich evidence for an implicit understanding of belief in infants as young as 13–18 months has been gathered with looking-time and anticipatory-looking methods, but also in interactive tasks requiring inferences about an agent's goals based on his or her beliefs (see Baillargeon et al. (2010) for a review). For example, Onishi and Baillargeon (2005) showed in a habituation task that 15-month-olds expected an agent who had or had not witnessed an unexpected transfer of an object from one location to another to reach into the location where the agent truly or falsely believed the object to be hidden, that is, the infants looked reliably longer when the agent reached to the other location. Longitudinal evidence indicates continuity between an implicit understanding of belief at 18 months of age and an explicit one at 48 months of age on a task-specific level (Thoermer et al., 2012). There is an ongoing debate about whether infants' success on implicit false-belief tasks is evidence for an implicit ToM or whether the findings can be accounted for by lower-level mechanisms such as statistical

learning (Ruffman et al., 2012) and the application of behavioral rules (see Sodian (2011) for a review).

The findings on infants' implicit understanding of false belief are part of a larger body of recent research on psychological reasoning in infancy. Two distinct conceptual systems have been claimed to support infants' reasoning about intentional action: one allowing the attribution of motivational states such as goals and dispositions and permitting the correct prediction of an agent's action when the agent's informational state corresponds to reality, and other allowing action prediction when the agent's informational state is incongruent with reality, as in the case of the agent holding a false belief. There is ample evidence for infants' propensity to conceive of human action in terms of action goals, even in the first year of life (see Woodward (2009) for a review): In Woodward's paradigm, 5-month-old infants were habituated to a hand repeatedly reaching toward and grasping one of two objects placed on the opposite ends of a small stage; in the test phase, the positions of the objects were reversed, and the hand now reached either for the previously grasped object on a new path or for the old object on the same path; infants showed stronger dishabituation to the new-object event than to the new-path event, indicating that they had represented the action in terms of its goal, not in terms of spatiotemporal properties. Further, infants as young as 6 months are able to keep track of what an agent can and cannot see when representing the agent's goal (Luo and Johnson, 2009). The ability to infer an agent's goals when observing a failed attempt and to analyze the goals of incomplete actions, as well as infants' understanding of action roles in social interaction and their sensitivity to others' motives provide evidence for the attribution of intentions to agents (see Poulin-Dubois et al. (2009a) for a review).

Joint attention, emerging toward the end of the first year of life, has been interpreted as an implicit ToM, since it involves the sharing of an experience with another person and therefore a sharing of perspectives. There is increasing evidence for this view from studies showing that 12- to 18-month-old infants use an adult's gaze direction to obtain information about objects outside their visual field, that they use the pointing gesture specifically to convey information, and that they represent what others have previously experienced (see Moll and Meltzoff (2011) for a review).

Infants' ability to communicate preverbally with others and to attribute goals and intentions to agents is a specific developmental precursor of later full-fledged mental state attribution: Several independent studies indicate significant predictive relations of social information-processing skills toward the end of the first year of life and ToM competencies in preschool age, independently of language abilities and IQ (e.g., Wellman et al., 2008). Similarly, joint attentional skills around the first birthday are predictively related to later explicit talk about the mind (Kristen et al., 2011). In sum, the longitudinal evidence, albeit still scarce, indicates conceptual continuity from an implicit to an explicit ToM in early childhood development.

Cultural Variation

A ToM is fundamental for human cognition. Therefore, it appears plausible that it should be universal. However, explicit ToM reasoning develops only in the preschool years and is closely related to language acquisition. Social influences, such as individual variation in maternal interaction styles, have been shown to be related to children's ToM development (Meins et al., 2002). Thus, there is reason to expect cultural variation in the timing of the acquisition of mental-state concepts. Still, if this variation is not very large, if false-belief understanding is acquired by all typically developing children of a culture within the preschool years, and if the sequence of acquisition of mental-state concepts is the same across cultures, we would take this as evidence for the universality assumption. Cross-cultural ToM research has addressed children's performance in ToM tasks across cultures, as well as their spontaneous construal of the mental domain in their developing mental state language. In contrast, to date very little research has addressed cultural variation in preverbal infants' psychological understanding.

Infancy

Recently, the first systematic study on cultural variation in early social-cognitive skills was carried out by Callaghan et al. (2011). In a series of eight studies, they assessed the social-cognitive skills of 1- to 3-year-old children in rural Canada, Peru, and India. Children's performance on basic joint-attention and intention-reading tasks such as imitation, helping, gaze following, and communicative pointing was similar across the three cultural settings. Similarly, children displayed much the same competencies in interactive episodes of collaboration and joint attention. Differences emerged only in symbolic skills, with pretense and pictorial skills emerging much earlier in the Canadian children than in the other two cultural groups. The authors conclude from these findings that children get enough social experience in all cultural settings to develop the most basic social-cognitive skills, but that the acquisition of more specific symbolic skills may be dependent on specific learning experiences that Western cultures amply provide.

Mental State Language

Toddlers' emerging spontaneous talk about the mind is an important source of evidence for their nascent *explicit* understanding of mental states. Based on an extensive literature search of mental state words and from natural speech samples, Bretherton and Beeghly (1982) created a 78-item parental checklist of mental state words. Overall, 28-month-olds produced terms from six categories. Thereby, their volition/ability vocabulary was most varied, followed by their physiological vocabulary and perceptual vocabulary. Children's emotion and affect and moral judgment/obligation vocabulary were more varied than children's cognition vocabulary, which significantly lagged behind all other categories. A longitudinal study examining mental state language in the home environment (Bartsch and Wellman, 1995) showed that children begin to use desire terms at around 18–24 months of age. Genuine references to cognitive states (e.g., "I know that the cat is in the garage") develop at around 3 years of age (e.g., Taumopeau and Ruffman, 2006, 2008). Concerning their relative frequency, beliefs and thoughts only begin to match desires at around 5 years of age. Across ethnic groups, the developmental pattern

applying to Caucasian-American children was found to be identical in African-American preschoolers (Curenton and Justice, 2004). The result that children acquire desire terms before they acquire belief terms can be generalized not only to different ethnic groups living in the same culture but also to other languages spoken within Western cultures such as German, Spanish, and French (Kristen et al., 2012; Pascual et al., 2008; Poulin-Dubois et al., 2009b).

Moving outside the boundaries of Western cultures, studies in Chinese children (Mandarin- and Cantonese-speaking) (Tardif and Wellman, 2000) demonstrated variation in the timing of the beginning and the end points of this developmental sequence as a function of linguistic as well as cultural factors. Carefully choosing languages (Mandarin and Cantonese) which produce a great number of contrasts when compared with English, a study by Tardif and Wellman (2000) assessed the development of mental state language in 10 Mandarin-speaking (21–27 months of age) and 8 Cantonese-speaking (8–44 months of age) children. The results suggest a pattern of development which is similar to the one observed in English, with early use of desire terms being followed by other mental state references. However, results also revealed cross-cultural variations. First, Chinese-speaking children were found to use desire terms much earlier than Anglo-American children. These findings were corroborated by studies showing that in Mandarin the term 'want' is among the first words that children use (Tardif et al., 1999). The authors conclude that Chinese children's overall attention to verbs and their early verb learning might account for their accelerated reference to desires as compared with English-speaking children (Tardif, 1996). Further, the term 'know' was referred to relatively early in Mandarin- and Cantonese-speaking children (before their second birthday), whereas Bartsch and Wellman (1995) found that American-English children acquired 'knowing that' closer to their third birthday. The authors discuss that the lack of a finite distinction and the lack of a complementizer after the Mandarine and Catonese verbs for 'know' make it easier for Mandarin- and Cantonese-speaking children to understand and express notions of 'knowing that' than for English-speaking children. Finally, the authors concluded that linguistic as well as cultural differences result in even later reference to 'thinking' in Chinese-speaking children than in English-speaking children. In contrast to English, containing mainly neutral terms to talk about beliefs, Chinese languages contain neutral as well as nonneutral belief terms (e.g., *yi3wei2* in Mandarin and *ji5wai4* in Cantonese) specifically marking someone's belief as false (Tardif et al., 2004; cited in Liu et al., 2008). In regard to possible cultural explanations for these differences, folk psychologies, societal expectations, and parental practices differ significantly between Eastern and Western cultures all of which could potentially affect children's developing talk of mental states. In specific, Chinese parents' disinclination to talk about 'thinking' with young children might account for them referring to 'thinking' later than English-speaking children (Liu et al., 2008).

In turn, internal state language might give insight into folk psychology in different cultures. In some languages, the contextual use of mental state terms might reflect cultural beliefs. For instance, the checklist developed by Bretherton and Beeghly (1982) has recently been translated into Dakota. The Dakota language represents one of the major three dialects (the other two being Lakota and Nakota) spoken by the Sioux, a Native American people in North America and is known to embody a value system about how to live and how to relate to each other, as well as describing the Dakota people's connection to nature, animals, the Great Spirit, and the order of things (Knudson et al., 2010). In the Dakota psychology, all creations (humans, animals, and the universe), while belonging to different building blocks of creation, are mentally connected. These relations are also reflected in small subtleties in the contextual use of mental state terms. For instance, while in English and other Indo-European languages the moral term 'mean' is mainly used in reference to people, in the Dakota language the term refers to both people and animals. *Wicaste kin canze* means the 'man is mean,' while *Sunka wan canze* means 'a dog is mean' (Canku and Kristen, 2013).

Mental State Reasoning in ToM Tasks

Two main issues have been addressed in cross-cultural ToM research: the universality of the acquisition of false-belief understanding and the universality of the order in which mental state concepts are acquired, with desire reasoning preceding belief reasoning.

Cross-cultural comparisons have been limited by small sample sizes and sample specificities. Therefore, Liu et al. (2008) conducted a meta-analysis of studies contrasting Chinese (i.e., Mandarin- and Cantonese-speaking) and North American samples. The meta-analysis consisted of 196 Chinese conditions (from Mainland China and from Hong Kong), representing responses from more than 3000 children, and 155 North American conditions. The findings showed parallel developmental trajectories of false-belief understanding for children in China and North America coupled with significant differences in the timing of development, with performances varying across different locales by as much as 2 or more years. More specifically, Liu and colleagues report that Canadian children show above-chance performance on false-belief tasks around the age of 38 months, whereas Hong Kong children do so around the age of 64 months. The authors conclude that these data show the importance of both universal trajectories and specific experiential factors in the development of ToM.

A similar variation in the timing of false-belief acquisition was found in non-Western cultures other than China. An early study by Avis and Harris (1991) in rural Cameroon yielded findings remarkably similar to those reported for European and North American samples. In a carefully adapted task, children saw an adolescent member of the community cooking kernels in a hut. After that, the adolescent placed them in a bowl and then left the room. In his absence, an adult entered the hut and conspired with a child to trick the adolescent by taking the kernels out of the bowl and putting them into a closed pot. The child was then asked where the adolescent would look for the kernels when he would come back. The authors found that preliterate Baka children in southeast Cameroon passed at an age comparable to that seen in European and North American studies. Consistent with the original experiment, 5- to 6-year-olds answered

correctly that the adolescent would mistakenly look for the kernels in the bowl. Consistently, Oberle (2009), who did research on the Micronesian islands of Yap and Fais and used a classical surprise-content task with culturally adjusted research materials, found that 3-year-olds did not display false-belief understanding, while 5-year-olds did.

In contrast, Vinden (1996) conducted a study of false-belief understanding and understanding of representational change with carefully adapted materials in 4- to 8-year-old Junin Quechua children in the Peruvian highlands. Performance on these tasks was poor even in 8-year-olds. One reason for this deviant developmental pattern may be the relative absence of explicit mental state vocabulary among the Junin Quechua. Surprisingly, some studies have also reported a marked delay in false-belief understanding in Japanese children. Naito and Koyama (2006) found that Japanese children understand false belief only at the age of about 6–7 years. This delay may be due to cultural attribution styles: children in some Asian cultures may be led to attribute behaviors (especially mistaken action based on a false belief) to social roles rather than to internal causes. Note, however, that the study by Naito and Koyama (2006) used careful translations but did not adapt the material to the cultural context. In any case, there is no generalized delay in Japanese children's grasp of epistemic cues: Matsui et al. (2009) found that Japanese 3-year-olds benefitted from the explicit statement of a speaker's false belief in a way that German 3-year-olds did not, when it was marked with a Japanese grammaticalized particle of speaker certainty. Nor is there an across-the-board delay in Asian children's performance on standard false-belief tasks: When comparing preschoolers from Korea with preschoolers from the United States on a set of false-belief problems (inanimate object, voluntary person movement, involuntary person movement), children from the Korean culture, which fosters a relatively interdependent conception of the self, were shown to outperform American children (Ahn and Miller, 2012). Overall, variations in children's relatively interdependent self-responses were shown to be predictive of good false-belief performance.

The most serious deviations from developmental synchrony as postulated by the universality assumption were found in studies of ToM development in Samoan children. Callaghan et al. (2005) investigated mental state reasoning in Canada, Peru, Thailand, India, and Samoa with a false-belief paradigm, which was held constant across cultures involving a change of location. In all the five countries, the majority of 3-year-olds significantly failed. In the group of 4-year-olds, the difference between those who passed and those who failed did not reach significance in all of the countries, with the exception of Samoa, where 18 out of 25 children still failed ($p < .05$). While the majority of the 5-year-old children clearly passed the task in Canada and Peru ($p < .001$), as well as in Thailand and India ($p < .01$), only 13 out of 18 children in Samoa passed the task ($p < .10$). To further explore this difference, Mayer and Träuble (2012) provided the first continuous survey of false-belief understanding beyond 5 years of age and tested more than 300 Samoan children using a change-of-location task. Samoan children improved gradually but rather slowly, with no succeeding majority before 8 years of age. One-third of the 10- to 13-year-olds still failed. Using a different translation among 55 children from 4 to 8 years of age resulted in the same results. The authors interpret their findings as supporting the cultural variability of ToM development: Samoans believe that it is impossible or very difficult to know what others think or feel (Robbins and Rumsey, 2008; cited in Mayer and Träuble, 2012). Due to this opacity-of-the-mind doctrine, mental states constitute no suitable object for conjecture in the Samoan culture and thus children may lack the learning experiences necessary to construct an explicit understanding of other minds.

To study cultural variation in the *sequence* of mental state comprehension, several studies used the ToM scale developed by Wellman and Liu (2004). This scale has previously been well validated and shown, via both Guttman and Rasch analyses, to identify a reliable developmental sequence of mental state concepts in which progress to any later scale step was contingent on mastery of all earlier ones. Preschoolers in the United States, Australia, and Germany mastered the steps in the following order: diverse desires, then diverse beliefs, then knowledge access, then false beliefs, and finally hidden emotions (Kristen et al., 2006; Peterson and Wellman, 2009; Peterson et al., 2005). When comparing Chinese-speaking preschoolers in Beijing and Iranian preschoolers with English-speaking preschoolers in the United States, the authors observed cross-cultural differences (Shahaeian et al., 2011; Wellman et al., 2006, 2011). Beijing and Iranian preschoolers reversed the diverse beliefs and knowledge access steps to reveal a scale sequence placing expertise with knowledge access (people who witness an event know about it) reliably ahead of diverse beliefs (different people have different ideas and opinions about the same thing). The authors concluded that these differences might be due to the emphasis on mutual respect and avoidance of dispute in collectivist cultures. Importantly, across all studies employing the ToM scale, the diverse-desire task was mastered before children mastered the false-belief task. Thus, the desire–belief sequence seems to follow a universal pattern.

Summing up, consistent with the findings of studies in early *mental state talk*, studies of ToM reasoning in non-English-speaking children indicate that the overall developmental sequence of *mental state comprehension*, with desire understanding preceding understanding of beliefs, is consistent across cultures. However, rather specific cross-cultural variation seems to exist in the onset of mental state comprehension. These temporal variations have been interpreted as an effect of cross-cultural input differences (e.g., emphasis of filial respect in a given culture).

Cross-cultural ToM research is, however, still limited by design problems. It seems warranted to conduct cross-cultural studies that allow us to investigate the effects of language, family input, and cultural beliefs in the same sample. While most studies interpret their findings in these terms, few studies have actually compared parental input and cultural representations of a ToM across Western and non-Western cultures, and related them systematically to interindividual differences in children's mental state production and comprehension across a broad range of categories within the same sample.

Furthermore, cultural variation in the relationship between ToM and its most important developmental correlates (e.g., inhibitory control) has rarely been studied. Existing research draws a differentiated picture. Chasiotis et al. (2006) found that conflict inhibition, but not delay inhibition, predicts false-belief understanding across three cultural contexts: Germany, Costa Rica, and Cameroon. However, another study found that Korean children display ceiling effects in inhibitory-control tasks before they pass false-belief tasks and that the relationship between inhibitory control and false-belief understanding is weaker in Korea than in Britain (Oh and Lewis, 2008). Thus, more research is needed to fully understand the effects of culture on the complex developmental mechanisms leading to the emergence of an explicit ToM in preschool age and to inform theories on the precursors of a ToM.

Therapeutic Community

Abstract

Therapeutic Communities are both a radical group-based therapeutic method, and a complex therapeutic philosophy. This article traces their sociopolitical history and describes the numerous influences which have been influential in the field's development. It distinguishes between the 'British Model' (mostly used in mental health settings) and the 'American Model' (mostly for addictions) and describes how they now share much of the same territory. The phases of treatment are explained, as are the indications and contraindications for their use. Evidence of effectiveness, together with suitable sources of further information, are given.

Defining Beliefs

Certain beliefs about human relationships and the nature of therapy are central to therapeutic communities.

- Staff are not completely 'well' and residents are not completely 'sick.' There is a basic equality as human beings between staff and residents, who share many of the same psychological processes and experiences.
- Whatever the symptoms or behavior problems, the individual's difficulties are primarily in his or her relationships with other people.
- Therapy is essentially a learning process, both in the sense of learning new skills – how to relate to others or deal more appropriately with distress – and learning to understand oneself and others.

The British Model

In the United Kingdom the term 'therapeutic community' is most commonly ascribed to Tom Main (1946), who used it in his description of the psychiatric hospital systems which emerged during the second World War for treating battle-shocked soldiers. David Clark (1964, 1965) later refined the term to distinguish the general 'therapeutic community approach,' which was then usually applied to the whole hospital, and 'the therapeutic community proper' – units which see themselves with a distinct identity and which have clear membership. The modern day equivalent term for the 'therapeutic community approach' is 'therapeutic environments,' which is becoming recognized – at least in the United Kingdom – as something that has been lost in various settings, such as hospital wards, day services, and community facilities. The therapeutic community proper is now more commonly called the 'democratic therapeutic community' in Britain, often abbreviated to 'DTC.'

Roberts defines a therapeutic community as

> a consciously designed social environment and programme within a residential or day unit in which the social and group process is harnessed with therapeutic intent. In the therapeutic community the community is the primary therapeutic instrument.
>
> Roberts, 1977: 4

These therapeutic communities are sometimes known as the 'Maxwell Jones Model,' 'mental health,' 'psychiatric,' 'flattened hierarchy' as well as 'democratic' type.

History

Despite the recent identification of therapeutic communities as a specific entity, their origins go back much earlier. 'Mentally afflicted pilgrims' attended the shrine of St Dymphna at Geel in Flanders in the mid-thirteenth century, and some commentators identified this as the first recognizable format reflecting the principles and practices of therapeutic communities (Parry-Jones, 1981). The pilgrims were taken in by the residents of the village, and cared for communally; their outcome criteria was the more weight pilgrims gained, the better the result! The next documented and identifiable strand of therapeutic community ideas emerged in 'moral treatment' in the eighteenth century. William Tuke founded the Retreat hospital in York in 1796, based on the development of his ideas on moral treatment. Tuke's particular approach was to treat the insane as closely as possible to how one would treat 'normal' people. Moral treatment is also particularly identified with Pinel, who referred to 'treatment through the emotions,' and practiced at the Salpêtrière in Paris in the early nineteenth century. These ideas crossed the Atlantic, and in 1817 a hospital was founded in Pennsylvania modeled on the Retreat by the Pennsylvanian Quakers (Tuke, 1813; Rothman, 1971; Scull, 1979).

Another therapeutic environment tradition which evolved independently is the field of therapeutic education for children. Bridgeland, in 1971, described residential therapeutic education as "a first attempt at combining psychotherapeutic ideas with participatory democracy" (Bridgeland, 1971). Homer Lane set up the 'Boys Republic' between 1907 and 1912 in Chicago for deprived urban children. He imported the idea into the United Kingdom in 1913 and set up the 'Little Commonwealth' in Dorset. This was also for disturbed youngsters (Bazeley, 1928). In 1924, A.S. Neill set up Summerhill School which continues to this day as an institution specializing in

 http://dx.doi.org/10.1016/B978-0-08-097086-8.27074-8

progressive education (Neill, 1937, 1967). These ideas were taken up by others, notably George Lyward with Finchden Manor (Burn, 1956), and David Wills and Marjorie Franklin with the Hawkspur and Q camp experiments in the 1930s (Wills, 1969; Franklin, 1966). Melvyn Rose adapted the ideas in the 1970s for the 'approved school' model for very disturbed children at Peper Harow (Rose, 1990). He ran this strictly as a therapeutic community, and the emerging ideas were also taken up by other approved schools, borstals, and probation hostels. A descendant organization from the Peper Harow Foundation, 'Childhood First,' continues to run residential therapeutic communities for children. Charterhouse Group is a similar organization (www.charterhousegroup.org.uk).

As well as therapeutic communities for disturbed children in the education field, there are also a number of communities for people with learning disabilities. The best known of these are the Camphill communities founded by König – which are based on the ideas of Steiner and his 'anthroposophy,' from which Montessori schools also owe an acknowledgment of their own theoretical base (Brendtro and Ness, 1983; Bloor et al., 1988). A similar, Catholic-based movement called L'Arche was founded by Jean Vanier in 1964 (Vanier, 1982). These two groups are closer in intention to the thirteenth-century caring communities in Geel, than to hospital or community-based treatment programs.

Another group of therapeutic communities was founded in the 1960s based on the radical ideas of the antipsychiatrists, particularly Ronnie (R.D.) Laing and David Cooper. The best known of these are the Philadelphia Association and Arbours Association in London, and Soteria House in the United States (Berke, 1982; Gunderson et al., 1983). Kingsley Hall, where the celebrated patient Mary Barnes was treated, was led by R.D. Laing between 1965 and 1970 (Cooper, 1967; Laing, 1971; Laing et al., 1965; Berke, 1980; Barnes and Berke, 1971). Both continue to this day: the Philadelphia Association as a housing organization; Arbours as a reputable psychoanalytic psychotherapy training institution.

However, most of the early therapeutic communities were found in the state psychiatric hospitals. The origin of democratic therapeutic communities is normally traced back to three experiments during the Second World War: two at Northfield Military Hospital in Birmingham and one at Mill Hill Hospital in North London (Harrison, 2000; Jones, 1946, 1968, 1979a). At Northfield, Bion's experiment with Rickman (Bion and Rickman, 1943; Bion, 1961) was stopped after 6 weeks when his work was more challenging than the military authorities would permit, as Tom Main later described

> neither the commanding officer nor his staff was able to tolerate the early weeks of chaos, and both were condemning and rancorous about Bion's refusal to own total responsibility for the disorder of others.
>
> Main, 1977

Bion was replaced by Main, Foulkes, and Bridger. This 'Second Northfield Experiment' continued with a less provocative and more integrated therapeutic community program until the end of the war (Bridger, 1946, 1985). Tom Main went on to be director of the Cassel Hospital at Richmond (Ham) in London, which for many years was a renowned intensive inpatient psychotherapy unit and only in the last decade has identified itself as a type of therapeutic community. S.H. Foulkes was another army officer running the second Northfield experiment, and he went on to found group analytic psychotherapy, culminating in the foundation of the Institute of Group Analysis in 1972 (Foulkes, 1948, 1964; Main, 1977). Harold Bridger died in 2005 after a long lifetime's work in organizational consultancy with the Tavistock Institute of Human Relations.

In 1941 at Mill Hill Hospital, Maxwell Jones (then an award-winning respiratory physiologist) saw that soldiers suffering from what was called 'effort syndrome' were more helpful to each other than the staff, by sharing the emotional meaning of their experiences in discussion groups (Jones and Lewis, 1941). After developing a successful short-term program based on this principle during the war, for a 100 or so men at a time, Jones later went on to set up the 'Industrial Neurosis Unit' in South London to get 'vagabonds and scroungers' back to work. This became the Social Rehabilitation Unit and later the Henderson Hospital, which was the flagship 'British Model' democratic therapeutic community proper from the 1950s (Jones, 1946, 1953, 1979b; Whiteley, 1980) until its closure in 2008.

Although Tom Main coined the term Therapeutic Community, it was Maxwell Jones whose name became most closely identified with the democratic therapeutic community movement – through the rapid growth and popularization of 'social psychiatry' in the 1950s. Between then and the 1970s, all the leading British psychiatric hospitals had wards operating as therapeutic communities. These include an early example of the fusion principle with Bertram Mandelbrote – an Oxford psychiatrist whose admission ward was Phoenix, but he also was responsible for founding the Ley Community, an addiction therapeutic community (Mandelbrote, 1965; Wilson, 1978). The therapeutic communities also moved out of the wards into the community and began to be applied to day units. Other nonhospital residential units also developed, for example Richmond Fellowship Hostels (Jansen, 1980).

Another development was in 1962 when HMP Grendon opened in Buckinghamshire, as a therapeutic community prison – not a drug rehabilitation wing, but as a mental health unit (Gunn et al., 1978; Morris, 2004). At the same time as HMP Grendon was established, Dennie Briggs opened Chino, a prison in California (Whiteley et al., 1972). Both were based on the Henderson model.

British-model therapeutic communities' fortunes in the prisons have waxed and waned for the last 40 years; HMP Grendon still exists with its six therapeutic community programs, as do several others in the British prison system: but as many others have come and gone over the same period, unable to adapt and survive sufficiently to a fundamentally authoritarian environment (Parker, 2007).

In 2000, two replicas of Henderson were set up: but they did not survive the first decade of the twenty-first century, as the expense of providing hospital beds became increasingly unacceptable to the funding authorities. Over the same period, a number of nonresidential units were established, including day units (most commonly operating 3 days per week), and

a few others using a 'low dose' treatment of 1 or 2 days per week.

Theoretical Foundations

In terms of theoretical underpinnings, Tom Main's approach was more explicitly based on psychoanalytic theory; the Henderson Hospital and other therapeutic communities were founded on a social learning/sociotherapy model. Group analytic theory offers a theoretical bridge between them, and many modern therapeutic community practitioners are trained in group analytic psychotherapy. The modern British therapeutic communities also incorporate and use a range of other therapeutic approaches, including cognitive and behavioral therapy; humanistic and integrative psychotherapy; art, music, movement, and the creative therapies; psychoeducation; systemic work with families; and other less mainstream ones (see Campling and Haigh, 1999). So a 'British Model Therapeutic Community' now describes the format of therapy – in groups and with a particular nature of relationships and democratic procedures – rather than a specific theoretical orientation.

The group-analytic based therapeutic communities have reached a very high level of sophistication and complexity which is perhaps best demonstrated by their extensive development in Greece, in organizations such as the treatment, training, and research communities of the Open Psychotherapeutic Centre and Kypseli in Athens, as well as the Department of Preventative Psychological Medicine in the Greek Navy (Kokkinidis, 1988).

The original definition of the British model comes from anthropological research at Henderson in the 1950s, to produce what have been called Rapoport's four 'Articles of Faith': *permissiveness*, *reality confrontation*, *democratisation*, and *communalism*. Permissiveness means that all members should tolerate one another; communalism suggests there should be tight-knit, intimate sets of relationships; democratization implies every member of the community (clients and staff) should share equally in decision making about community affairs; and reality confrontation suggests residents should be continually presented with interpretations of their behavior as it is seen by others, in order to counteract their tendency to distort, deny, or withdraw from their difficulties in getting on with others (Rapoport, 1960).

Haigh (1999) brought together various psychological and sociological theories to explore a necessary sequence of experiences for 'secondary emotional development' (as in a therapeutic community), and how this might relate to 'primary emotional development' (as in all successful human growth). The five sequential 'principles' are attachment, containment, communication, inclusion, and agency, with corresponding 'cultures' of belonging, safety, openness, involvement, and empowerment.

The American Model

In 1958, a new kind of therapeutic community was created in America, by the forceful personality of its originator: Chuck Dederich. He started by setting up a weekly group for helping ex-Alcoholics Anonymous members and ex-addicts in his own flat, based around free association, 'attack' therapy groups or 'Synanons,' and educational seminars, particularly based on philosophical ideas. This was the beginning of Synanon, and it was the first of what came to be known as 'concept-based,' 'hierarchical,' 'behavioral,' or 'programmatic,' and more recently 'addiction,' therapeutic communities. They were self-help communities, created by ex-alcoholics and drug addicts, which were called 'concept-based' because they referred to a set of explicit concepts about the nature of drug addiction and its treatment, based on psychological explanations of the causes of drug addiction and how a therapeutic community could help people live drug-free lives. The concepts are based on three main themes: those which explain the nature of the addict's problems; those which demonstrate how therapy works; and those which underpin how the addict should behave in the therapeutic community (Kennard, 1998). Another of the major characteristics of Synanon was its profound antiprofessionalism, with emphasis on self-help, including taking responsibility for one's situation, and the inclusion of nonaddict community members ('straights,' 'lifestylers,' and 'squares') (Casriel, 1963; Yablonsky, 1965).

Although the original group developed out of contacts through AA, Synanon eventually became concerned mainly with the rehabilitation of ex-drug addicts. It developed a very explicit program revolving around the highly confrontative encounter group called the 'game' or the 'stew,' based on the notion of 'no-holds-barred' honest confrontation, and particularly the challenging of emotional defenses, or 'cop-outs.' Communities had a very strict hierarchical structure, up which newcomers had to slowly work their way. The communities also functioned to a model of an autocratic family structure.

Synanon communities proliferated, but in 1963 a derivative of Synanon also developed – the Daytop village ('DAYTOP' stands for Drug Addicts Treated On Probation), which was started by a team of psychiatrists and probation officers who had been impressed by a visit to Synanon (Casriel, 1971; Sugarman, 1974). In 1968, another major therapeutic community organization was set up – Phoenix House, New York (Biase and Rosenthal, 1969). It became the largest and best known concept house, with places for about 400 residents at any one time (De Leon, 1973). In 1970, three graduates from Phoenix House came to London and set up a concept house with Griffith Edwards, at the same time as Ian Christie was setting up Alpha House in Portsmouth (Kooyman, 2001); others were later set up throughout the United Kingdom.

The spread of addictions therapeutic communities across the world has been considerable in the last two decades. There are now six organizations in world regions to coordinate activities. The Federation of Latin American Therapeutic Communities covers South America, and they now have more than 600 programs in over 20 countries. The Asian Federation of Therapeutic Communities covers the whole of Asia, and gives its main current preoccupations as war, the easy availability of very pure heroin, and very little coordination of responses to the problems. The European Federation of Therapeutic Communities covers Western Europe and has an extra 'European ingredient,' probably related to its separate roots in

psychoanalysis, critical theory, and sociology – for example, the work of Foucault and Lacan; it is also closely related to the European Working Organisation for Drugs-Orientated Research. The Federation of Therapeutic Communities of Central and Eastern Europe now covers communities in Eastern Europe, and has a flavor more of 'action learning' – by communities undertaking vigorous outdoor activities in their programs. Geographically most remote, there is the Australasian Therapeutic Communities Association, which was founded in 1986 and covers Australia, New Zealand, and Papua New Guinea. Therapeutic Communities of America covers the United States, Canada, and Mexico.

The American addiction therapeutic community treatment model is based on a number of concepts:

- Self-help
- The use of community as method
- Safety in acceptance
- Hierarchical structure
- Verbal reprimands and learning experiences
- Encounter groups
- Family work
- Drug abstinence
- Social confidence training
- Relating

The last few years have brought about some changes. These 'changed' therapeutic communities are referred to by, for example, Broekaert et al. (2006) as 'the new therapeutic communities' and have largely developed in terms of complex networks dealing with special needs and specific target groups. They have included treating different types of people, such as people with dual diagnosis, children of abusers, homeless people, those with posttraumatic stress disorders, immigrants, prostitutes, HIV sufferers, and street children in Latin America.

The 'Fusion' Model

The history of the two traditions of the main types of therapeutic community shows that very different models are now coming together, in the face of similar challenges (Haigh and Lees, 2008). In the past, the differences were more stark, but changes in the political and social context have influenced the programs in both main types of therapeutic community: some former therapeutic community practices are no longer regarded as acceptable; client rights and the health consumerism have changed treatment practice; there is increasing professionalization of staff, together with increased employment of ex-service users in both types of therapeutic community. Both types are also increasingly finding their target client groups that are ever more similar: more people entering democratic therapeutic communities have addiction issues, and more people entering addiction therapeutic communities have mental health issues. Both types have more structured programs, treatment times, and clear career progressions through treatment for clients, as well as extensive after-care provision. Both emphasize the importance of the therapeutic community as the mode of treatment (De Leon's 'community as method'), and the importance within this of the emancipatory use of groups and peer therapy. The successful growth in Europe and Australasia of therapeutic communities which deliberately combine the democratic and addiction models has led to a strong hybrid, with strengths from both and without some of the problems associated with thoroughbreds. They offer a model for the future development, and possible protection, of therapeutic communities.

Pathways and Process: Phases in the Therapeutic Journey

There are usually four distinct but overlapping phases in a member's journey to and through a therapeutic community.

Engagement Phase

Referral, preparation, and selection procedures are an integral part of therapeutic community practice, involving both the prospective member and existing residents as active participants in the process, which start with referral or self-referral. Many prospective members of therapeutic communities are wary or fearful of the forthcoming therapy, and need support and encouragement to persist.

Assessment and Preparation Phase

When a decision to proceed toward formal treatment has been made, several arrangements may be needed. These include formal assessment processes, practical planning, and agreeing a treatment contract. This work is frequently arranged through the use of an 'assessment and preparation group,' which is also designed to be a time-limited foretaste of what the treatment phase entails.

Treatment Phase

This usually begins with a formal 'case conference' or 'selection panel' including current community members with a decision made by voting. Subsequent therapy programs vary considerably: from 1 day per week to whole-time residential; from predominantly sociotherapy to a range of psychoanalytic, cognitive-behavioral, humanistic and interpersonal, and systemic groups; from a few weeks duration to several years, either time-limited or open-ended; and from group size of less than six to more than 50. Some communities include individual therapy, but others consider this inimical to the group dynamic process. A modal or typical program would be for between 3 and 5 days per week, with all interventions in groups comprising a mixture of community meetings, small therapy groups, shared lunch, and informal time together.

Recovery Phase

Until recently, many therapeutic communities had a 'cliff-edge' ending, where one day members are able to have the community's full emotional and practical support, and the next day are not allowed to contact any other members. Although this

has some theoretical justification in terms of 'coming to term with endings,' and has strong advocates among ex-members of therapeutic communities, it is now generally considered better practice to support members over the leaving process, and then into re-establishing mainstream social networks. This can be done with a specific 'leavers group,' that members join while in the full treatment phase and continue afterward, for either a fixed or indefinite period. These groups normally include a practical focus, and are social and supportive rather than exploratory and therapeutic. For those who are ready and able, they can have objectives of securing employment or education for members.

Evidence

Personality Disorders

While efficacy in the treatment of personality disorders (PD) is still questioned, the picture has recently become clearer with the publication of the first systematic review of therapeutic community treatment for people with personality disorders (Lees et al., 1999). A meta-analysis found that 19 studies showed a positive effect within the 95% level of confidence while the remaining 10 straddled the neutral score. The authors concluded that there is strong evidence for the effectiveness of therapeutic communities. A more recent systematic review assessed evidence for interventions for people with PD in general and for dangerous and severe personality disordered offenders and made clear recommendations about the most promising treatment interventions for PD in use or currently in development. They concluded that "the TC model currently has the most promising evidence base in this poor field" (Warren et al., 2003).

Offending Behavior

Therapeutic communities have been established in prisons to deal with disruptive, violent inmates and also with the underlying problems of antisocial PD. Results at Barlinnie Special Unit in Scotland demonstrated substantial reductions in violent incidents within prison. Reconviction studies carried out at Grendon, a prison run entirely on therapeutic community lines, found that prisoners had lower rates of reconviction, fewer custodial sentences, and fewer reconvictions for violent offenses than prisoners on the Grendon waiting list who never went there. Those who stayed at Grendon longer than 18 months showed the greatest reductions in reconviction rates. Reoffending rates have also been found to be lower in the former Federal Republic of Germany for prisoners in Social Therapeutic Institutions than those receiving standard prison sentences (Rawlings, 1999). In 2004 the 'Democratic Therapeutic Community Core Model' was accredited as a treatment program for use in prisons in England and Wales. Such programs must show evidence of their capacity to impact on dynamic risk factors known to be associated with reoffending. Risk factors that therapeutic communities have been found to have a positive influence on include negative attitudes toward authority, identification with antisocial role models, and acceptance of responsibility for offending behavior.

Drug Dependence

Therapeutic communities for drug dependence use the hierarchical or concept-based model. These form one part of the range of treatments for drug abuse, which includes other residential models such as Christian communities and the Minnesota model, as well as methadone maintenance programs, and psychotherapy. Therapeutic communities for drug dependence, often modified to suit different local cultures, can now be found in many European and international countries as well as in the United States where they originated. Several national studies have evaluated the outcome of these programs. Randomized controlled trials show that no-treatment groups have a higher level of recidivism than those who complete treatment in a prison therapeutic community, and that recidivism is further reduced by participation in a aftercare therapeutic community (Wexler, 1997). Since 1995 a number of these therapeutic communities have also been established in English prisons. The general conclusion, for both secure and nonsecure therapeutic communities, is that residents who stay in programs for longer periods have lower rates of drug use and criminal behavior and higher rates of employment than those who stay for shorter times.

First Episode Psychosis

A small number of therapeutic communities have been developed in the United Kingdom, the United States, Switzerland, and Germany on the principle that first episodes of psychosis can be effectively treated in low-stress family-like settings providing round the clock personal support, with no or minimal use of neuroleptics. This has become known as the Soteria model. Two Soteria houses, in California and Berne, have been subjected to randomized or matched control trials comparing them with usual hospital treatment. One study found that completing subjects with schizophrenia exhibited a large effect size benefit with Soteria treatment, especially in the areas of psychopathology, work, and social functioning. Length of stay in Soteria Berne was initially longer but this was subsequently reduced to less than the admission ward. In both studies the 2-year outcomes were at least as good in the Soteria group and less antipsychotics were prescribed for the Soteria group (Ciompi and Hoffman, 2004). A 20-year study of an acute psychiatric ward in Finland found that people with acute psychotic episodes and borderline conditions seemed to benefit from the therapeutic community model with a high level of support, negotiation, order, and organization.

Severe and Enduring Mental Illness

The therapeutic community approach (Clark, 1965) has been widely used in large mental hospitals to counter the effects of institutionalization and to mobilize the residual capacity of those suffering from chronic mental illness for social relationships, purposeful employment, and personal responsibility. With the reprovision of services for people with enduring mental illness in the community, therapeutic community principles have been found to be an effective way of structuring staffed hostels and homes. In one version of this, the 'ward in

a house,' the model is close to the original practice of the York Retreat, an antecedent of therapeutic communities (Leff and Trieman, 1997). The challenges presented by the severely mentally ill chemical user have also been addressed using a modified therapeutic community with some evidence of success. Three main modifications required to the TC structure were increased flexibility, decreased intensity, and greater individualization (Sacks, 2000).

Children and Adolescents

Therapeutic communities for children and adolescents exist for a variety of needs: learning disability, delinquency, and emotional disturbance. Little systematic evaluation has been carried out. A survey of 186 children in 9 therapeutic communities for emotionally disturbed children found evidence of increased stability and hopeful outcomes for those who stayed. A 20-year follow-up of 28 children in one community reported evidence of long-term improvement (Rose, 1997).

Wright and Richardson, reviewing the current state of research for therapeutic communities for children and young people, conclude that, "when rigorous quality controls are introduced there are as yet too few studies to draw any aggregated conclusions. Perhaps the clearest qualified statement would be that there is low level evidence that some residential therapeutic placements produce changes in the mental and social functioning of some young people who have been unable to cope with family life" (Wright and Richardson, 2003).

Learning Disabilities

Long-term residential communities for adults with learning disabilities exist in the charitable sector in many countries around the world. These are value based rather than evidence based. There is some evidence that many families express a strong preference for village-style communities such as the Camphill for their mentally handicapped relatives (Cox, 1995).

Therapeutic Effectiveness Assessment: Approaches in Contemporary Research

Mihaela Matei, Centre Européen d'Etudes et de Recherche Droit et Santé, Université Montpellier I, France

Abstract

Today, the way in which therapeutic effectiveness is assessed is once again subject to criticism. Burdensome bureaucratic regulatory procedures in traditional clinical research, the costs of health care systems, and the uncertainness as to the most effective treatment options available have raised significant questions about whether traditional research methods, such as randomized controlled trials (RCTs), can adequately address the contemporary issues posed by the health care systems. In particular, the recent development of health economics-related research demonstrated the limitations of RCTs as research methods (Kumar, 2013), widely criticized for its incapacity to reduce uncertainty about relative effects of treatments in individual patients. In order to better inform decision-makers clinicians as well as patients on the best practices available, the health economic studies pointed out the need for developing new research methods and designs more likely to provide evidence-based information on the effectiveness, benefits, harms, and costs of different treatments. These changes in clinical research designs and methods of evaluation of therapeutic effectiveness raise new ethical concerns and regulatory questions that need to be addressed properly. Recent initiatives to revise the legislative and regulatory framework for biomedical research (USA, EU, and France) directly tackle some of these issues. After describing contemporary advances in types of research on therapeutic effectiveness, this article will give an overview of the ongoing revision of the regulatory and legislative framework in the USA, EU, and France with a special focus on the way these initiatives address the legal and regulatory issues raised by the therapeutic effectiveness evaluation.

Currently new types of research that focus on the evaluation of treatment effectiveness – such as comparative effectiveness research (CER), patient-led research (PLR), or Internet research – are offered alongside classical randomized controlled trials (RCTs). These approaches open up new possibilities of assessing the therapeutic effectiveness of patient care in conditions that are more representative of the 'real world' (Chang and Winkelmayer, 2012). First of all, in contrast to traditional clinical trials which remain the gold standard for showing the safety and efficacy of a new medicinal product 'under ideal conditions' (Kumar, 2013), these new types of research are intended to more accurately reflect the effectiveness of therapies delivered in typical clinical practice. For example, in the case of CER, the evidence is generated through studies that compare two or more alternative tests, therapies, or procedures, most of which are routinely used in clinical settings. In particular, there is a growing interest in development of research on usual care, which is intended to assess which treatments are most effective in routine care. Subsequently, the new models attach utmost importance to the role of practice in the development of generalizable knowledge: "practice is a continuous source of data for the production of generalizable knowledge and the knowledge that is produced is used to continuously change and improve practice" (Kass et al., 2013). In addition, in order to fill in gaps in patient health information, researchers claim access to all of the available evidence: data from existing clinical trials along with data available in patient health records and patient-generated data outside of clinical settings. The development of a field of research such as Internet research may facilitate the collection of this type of health data and help researchers to fill in these gaps.

These changes in clinical research designs and methods involve a more comprehensive clinical data-sharing system, interventions at the cluster level, and direct patient involvement in the conduct of research projects, which in turn raise new ethical and regulatory questions that need to be addressed properly.

In particular, these changes challenge the capacity of the current research ethical and regulatory paradigm, which is dominated by the sharp distinction between research and clinical practice, to foster new types of research which links the two activities (Solomon MZ and Bonham AC, 2013). Subsequently, many authors argue that a new ethical foundation needs to be developed in order to facilitate *both care and research likely to benefit patients* ("Hastings Center Special Report of Ethical Oversight of Learning Health Care Systems, pp. S2 to S44," 2013). The new paradigm should abandon the 'faulty distinction' between clinical research and clinical care activities as well as the research ethical oversight based on this distinction in favor of a new framework integrating medical research and practice (Kass et al., 2013).

In spite of these arguments, recent initiatives to revise the legislative and regulatory framework for biomedical research (USA, EU, and France) tend to take a less radical position by proposing a new regulatory paradigm based on a risk-based approach without abandoning the distinction between research and practice. The creation of a minimal risk research category to which applies a risk-adapted oversight is intended to facilitate the assessment of therapeutic effectiveness.

After describing some of the contemporary advances in types of research on therapeutic effectiveness, this article will give an overview of the ongoing revision of the biomedical research regulatory and legislative framework in the USA, EU, and France with a special focus on the way these initiatives address the legal and regulatory issues raised by the therapeutic effectiveness evaluation.

Comparative Effectiveness Research

CER is largely recognized as a prominent method for the assessment of therapeutic effectiveness, especially when

standard clinical trials have important methodological limitations. In contrast to traditional RCTs, which focus on novel interventions, CERs often target existing therapies and widely adopted clinical practices in which there is clinical uncertainty about best treatments (Kass et al., 2013). Even though the concept of CER is not new, it only became a topic of priority in 2009, when President Barack Obama enacted into law the American Recovery and Reinvestment Act, which allocated 1.1 billion US dollars to CER studies.

The US Institute of Medicine (IOM) provided a comprehensive definition of CER: *CER is the generation and synthesis of evidence that compares the benefits and harms of alternative methods to prevent, diagnose, treat, and monitor a clinical condition or to improve the delivery of care*. According to IOM, the key goal of CER is assisting consumers, clinicians, purchasers, and policy makers to make informed decisions that will improve health care at both the individual and population levels. In addition, CER aims to inform policy decisions about health care utilization in terms of cost-effectiveness and how to prioritize the use of public funds in particular with regard to "areas where private incentives are low relative to social benefits" (Meltzer et al., 2010).

The Agency for Healthcare Research and Quality defines two ways in which evidence can be found through CER ("Methods Guide for Effectiveness and Comparative Effectiveness Review. AHRQ Publication No. 10(14)-EHC063-EF. Rockville, MD: Agency for Healthcare Research and Quality. January 2014. Chapters available at: www.effectivehealthcare.ahrq.gov," 2014):

> *research reviews* consist in the systematic reviewing of existing evidence (e.g. analyses of the available evidence about the benefits and harms of each choice for different groups of people from existing clinical trials, clinical studies, and other research).

> *studies* that generate, prospectively, *new* evidence of effectiveness or comparative effectiveness of a test, treatment, procedure, or healthcare service.

An example of CER is the comparison of AMD treatments trials (CATT) study (Rosenfeld, 2011) which compared two anti-VEGF (vascular endothelial growth factor) drugs used in the treatment of age-related macular degeneration, a disease causing irreversible blindness. The trial showed ultimately that both drugs had the same effects on benefits and harms. This trial could have a great economical impact, as the cost of these two drugs is remarkably different (US $2000 versus $50).

The study by Hejblum et al. (2009) – the comparison of the use of daily routine chest radiographs in 21 ICUs to on-demand x-rays for mechanically ventilated patients – could also have consequences on health economics. Results showed that the number of x-rays that led to or contributed to therapeutic or diagnostic interventions were the same in both groups, as well as mortality and length of stay. Despite that there was a reduction of 30% of the number of x-rays in the group on demand.

Prospective observational cohorts are another example of CER. Generally they are easier to run, cost efficient, and closer to 'real life' than classical randomized studies. Despite their methodological limitations, well-done observational studies proved, in many instances, to be as efficient as RCTs (Benson and Hartz, 2000; Concato et al., 2000).

In the US, the IOM set up a list of priority research topics that should be addressed in order to improve health care through CER. Among these topics, therapeutic effectiveness assessment is central. For instance, the IOM's list includes comparisons of the effectiveness of the different assistive listening devices like cochlear implants, electric acoustic devices as well as various treatment interventions in eradicating methicillin-resistant *Staphylococcus aureus* in communities, institutions, and hospitals. It includes also different strategies for localized prostate cancer and comprehensive care coordination programs, such as usual care in managing children and adults with severe chronic disease, especially in populations with known health disparities, etc. (IOM, n.d.).

In view of these examples, CER can take many forms: retrospective data analysis, systematic reviews of literature, as well as prospective studies, at both individual and cluster levels. For example, cluster randomized trials (CRTs) became an increasingly important method of assessment of treatment effectiveness, since the research interventions in cluster trials may be directed at social units such as hospitals wards, classrooms, primary care practices, and communities (Weijer et al., 2011). As Weijer and colleagues explained, the CRT is more appropriate than an individually randomized trial in many circumstances – when the nature of intervention targets entire communities, in the case of training or education of health professionals, and when investigators desire to reduce the effect of the so-called 'treatment contamination' (i.e., for instance, the interferences between tested patients and controls). A fourth circumstance identified by the authors is when investigators wish to study both individual and group effects of an intervention.

Despite the growing interest in CER, studies carried out on the feasibility of this type of research have shown that the current ethical and legal framework discourages its implementation. Subsequently, there is a significant debate about appropriate oversight required by CER. It is commonly argued that the ethical regulatory oversight should be refocused on specific features of CER (Platt et al., 2014).

For example, research on usual care is not easy to perform since its evaluation is subject to the same level of regulatory and administrative burdens as experimental interventions. Another major question is whether informed consent should always be required for this type of research, since in most cases the intervention added (e.g., randomization) by research bears only minimal risk and has little effect on the patient's usual care. Is it ethical to perform usual care research without written consent when patients are randomly assigned (Faden et al., 2014)?

Another example is CRTs. Monica Taljaard and colleagues (Taljaard et al., 2013) argue that these trials have unique features due to substantial methodological differences between CRTs and conventional randomized trials: *differing units of allocation (for example, hospitals), intervention (for example, health professionals), and outcome measurement (for example, patients) within a single study*. As a consequence, standard ethics guidelines for research are not adapted to CRTs. In the absence of

specific ethical guidelines, a research team comprising 15 investigators from Canada, the UK, and the US developed international guidelines for CRTs, known as the 'Ottawa Statement' (Taljaard et al., 2013). It sets out 15 recommendations in the form of a checklist that may be used by researchers in ethics applications: justification of the CRT design, research ethics review, identification of research participants, informed consent, role of gatekeepers, evaluation of benefits and harms, and protection of vulnerable patients. With regard to informed consent, the recommendations define the conditions under which the waiver of consent is ethically acceptable: *Waivers or alterations of consent can be justified only when the study would not otherwise be feasible and when the risks involved are minimal* (recommendations 6 and 7).

From a legal and regulatory standpoint, it has been suggested that the best way out would be to increment a risk-based regulatory approach according to which ethical review is determined based upon the level of risk posed to the studied participants. In the light of this paradigm, CER involving no more than low risk should be reviewed according to a simplified procedure. For instance, in France, some of these legal and regulatory issues raised by research on usual care were first addressed in 2004. The current French legislation ("Loi no 2004- 806 du 9 août 2004 relative à la politique de santé publique," 2004 codified in the French Public Health Code) authorizes investigators to carry out clinical research on usual care involving negligible risks without requiring patients' consent. Even though the written consent is not legally required in this case, patients have to be informed and have the right to object to their inclusion in the study as well as the right to withdraw at any time. Currently, in France there is a legislative revision on the way which is intended to adapt the review of this type of research to the level of risk added by research to usual care.

Despite its practical benefits, CER also has limitations. For instance, ethical concerns are raised by the use of CER results to determine how to prioritize the public spending on health care. In addition, CER also faces some methodological challenges due to its attempt to produce evidence from secondary data sources or nonrandomized data: *it relies heavily on unverifiable assumptions that are required for the method to give a correct answer* (Edward L. Korn and Boris Freidlin, Methodology for Comparative Effectiveness Research: Potential and Limitations) (Marc L. Berger et al., Good Research Practices for Comparative Effectiveness Research).

Internet Research and Data-Sharing Initiatives

The development of 'Internet research' (Markham and Buchanan, 2012) not only as a tool but also as a field of research also contributes to the evaluation of therapeutic effectiveness in a more rapid and easier way. Therefore, compared to other modes of data collection, the Internet is considered by some researchers to be a democratized way of data collection, giving access to large databases of health data, produced and collected in both clinical and research contexts.

On a purely clinical level, the implementation of electronic medical records has helped clinicians develop programs that collect data on clinical outcomes and to use this information in order to improve quality and safety for their patients. In terms of research as well, many data-sharing initiatives tend to expand public access to raw (participant-level) data from drugs and devices trials (Peloquin et al., 2013). One of the potential benefits of accessing large health databases and data sharing is allowing independent researchers to check on clinical trial results by replicating analyses with the use of raw data. Other benefits would be to *increase the precision of estimates of treatment efficacy, detect safety problems unobservable in smaller samples, allow exploration of subgroup effects, and permit analysis of how therapeutic effects vary in different geographic settings because of such factors as population genetics and health care delivery systems* (Mello et al., 2013). Because of the therapeutic benefits of analyses based on the existing data, and the will not to expose patients to any further physical risks, data-sharing initiatives are regarded as ethically acceptable. Nevertheless, these initiatives raise additional practical and ethical issues: the extent to which considerations of informed consent would be taken into account when individual-level data are released, concerns about the risk of patients reidentification, questions about the ethical oversight required by data-sharing models, etc. (Peloquin et al., 2013).

The Patient-Led Research

The traditional research field centered on the investigator/sponsor team has expanded to 'patient-centered' (Kaye et al., 2012) or 'patient-led' (Vayena and Tasioulas, 2013) research methods, allowing practitioners access to new types of data on relative health outcomes and clinical effectiveness of medical treatments. Defined as *tools, programs, and projects that empower participants to engage in the research process* (Kaye et al., 2012), PLR relies heavily on patient involvement in the conduct of research projects. This emerging model is defined as a complementary approach to traditional research since PLR allows individuals to share information on their conditions (self-reporting data) and investigators to *gather data that standard research systematically overlooks (e.g., drug side-effects or off-label uses)* (Vayena and Tasioulas, 2013). It is also intended to make patients' consent more readily obtainable, *as participants can be directly approached for consent to the use of their identifiable information for new research purposes* (Vayena and Tasioulas, 2013). However, the PLR method raises important questions about its capacity to achieve the scientific rigor needed to complement conventional investigator-led research.

The 'Learning Health Care System'

In 2007, the US IOM called on health care providers to change the health system into a 'learning health care system' (LHS) (Institute of Medicine (US) Roundtable on Evidence-Based Medicine, 2007). This new framework is intended to provide constantly updated evidence about health care interventions and their effectiveness. The LHS is mainly defined as theoretical and ethical alternatives to the sharp research-treatment distinction, and is justified by the growing number of activities that cannot easily be classified as either research or therapy: quality improvement activities, CER, practice-based research,

building of networks, and large databases of aggregated health care data, etc. Faden et al. argue that it is useless in most cases to try and distinguish research activity from clinical practice: *all such activities are learning activities* (Faden R.R., et al., 2013). By contrast, the LHS model sets a 'moral' priority on 'learning' health care activities that integrate research and clinical practice. More specifically, the LHS involves an interconnection of learning activities that combine observational research, CER, reviews of medical records, as well as the creation of registries alongside delivery of medical care.

The scientific evidence generated by the interconnection of these activities requires a greater access to health data, including to patient-level clinical trials data. Accordingly, the LHS model *urges a new ethical foundation, based on evidence-based practice decisions guided by the general knowledge produced from data collection activities essential to learning health care systems rather than on the research–practice distinction* (Largent et al., 2013).

From a legal and regulatory standpoint, one of the major impediments to the LHS model is the legal and regulatory framework pertaining to the use and reuse of clinical data. The current frameworks allow clinicians to share patients' health data with other clinicians, only under strict conditions, because of data protection rules and the risk of identification. Similar concerns around patient consent, privacy, and legitimate reuse need to be addressed with regard to the greater access and the sharing of clinical trials data, in particular of raw data. The impact on the sponsors' ability to patent inventions is another concern raised by the public disclosure of clinical trials. There is currently a worldwide effort at addressing these issues (Mello et al., 2013). Special attention is paid to the issues raised by public access to raw data, such as patient privacy, commercial interests, standardization, and quality. At the European level, the new EU clinical trials regulation imposes upon the sponsor the obligation to publish a summary of the results from clinical trials within a year of the trial's end. In addition, the EU regulation states that access to raw data should be permitted by the sponsor on a voluntary basis. The European Commission shall produce guidelines for the formatting and sharing of those data. In addition, the European Medicines Agency (EMA), which approves drugs for marketing within the EU, has proposed the expansion of access to data submitted in clinical trials' regulatory applications. The EMA announced in a draft policy in June 2014 that it will provide public access to some of the data in marketing dossiers, including participant-level data. Some of the data and documents will be published online excluding the raw data. The access to raw data will be controlled. Similarly, in the US, the Food and Drug Administration published in June 2013 a proposal to release deidentified participant-level data requesting public comments on its proposal.

In the light of these initiatives, the move toward greater transparency in the area of clinical data appears irrevocable.

The Necessity of Revising Existing Legislation and Regulation

Finally, these contemporary advances in therapeutic effectiveness assessment raise significant questions as to whether or not the current research legislation and regulation have kept pace with this evolution.

There is currently a worldwide effort at revising the biomedical legislation by using a new paradigm, which is commonly called the 'risk-based approach.' The issues raised by the evaluation of treatment effectiveness represent, to a great extent, the starting point for these legislative reforms.

For example, many academic sponsors have pointed out that the current legal and regulatory frameworks are not adapted to the research on existing therapies. One of their major critics is that the current legal provisions *apply largely irrespectively to risk to subject safety and without matching practical considerations and requirements* (European Commission, 2012a), in a 'one size fits all' manner (OECD, 2013). A report from the OECD (OECD, 2013) recommended that legislations on research should first establish a categorization of risks by taking account of the status of the medical product (authorized, off-label, innovative) as well as the invasiveness of additional procedures, the vulnerability of participants, and the deviation from usual practice. Secondly, they should adapt the regulatory requirements to that level of risks.

At the European level, the EU Commission has likewise advocated a risk-adapted approach to regulating research in its proposal of 17 July 2012 for a Clinical Trials Regulation (Reith et al., 2013; Markham A and Buchanan E, 2012). Although the scope of the proposal is limited to clinical research on medicinal products, the Commission faced multiples challenges. For instance, in its "Impact assessment report on the revision of the 'Clinical Trials Directive' 2001/20/EC" (DIRECTIVE, 2001/20/EC, 2001) the EU Commission recognized that the directive has been responsible of hindering therapeutic effectiveness assessment, both in terms of regulatory burdens and costs for administrative requirements. There has been a particular criticism of academic sponsors who are more likely than 'commercial sponsors' to carry out clinical trials on authorized drugs in order to improve the effectiveness of current treatments. In response to this, on 17 July 2012, the Commission adopted a Proposal for a Regulation (European Commission, 2012b) of the European Parliament and of the Council on clinical trials on medicinal products for human use, and repealing Directive 2001/20/EC, in which the Commission recognized that clinical trials on medicinal product that are covered by a marketing authorization or used according to published scientific evidence *are often of crucial importance for assessing standard treatments and diagnoses, thereby optimizing the use of medicinal products and thus contributing to a high level of public health.* The proposal was submitted to the European Parliament and Council who engaged in ordinary legislative procedure. After being largely modified, the final text of the new Clinical Trials Regulation, once voted, was published in the Official Journal on 27 May 2014 (European Parliament and Council, 2014).

The new European regulation is intended to facilitate the clinical trials on medicines that pose only minimal risks to subject safety compared to normal clinical practice. Accordingly, the regulation establishes a risk-based clinical trials typology and calibrates regulatory burdens to the level of risk involved by the research. For instance, specific provisions are intended to ease the monitoring, vigilance, traceability, and damage compensation, in clinical trials with 'low intervention.' The 'low intervention clinical trial' category covers clinical trial which fulfills all of the following conditions: *(a) the investigational*

medicinal products, excluding placebos, are authorised; (b) according to the protocol of the clinical trial, (i)the investigational medicinal products are used in accordance with the terms of the marketing authorisation; or (ii) the use of the investigational medicinal products is evidence-based and supported by published scientific evidence on the safety and efficacy of those investigational medicinal products in any of the Member States concerned; and (c) the additional diagnostic or monitoring procedures do not pose more than minimal additional risk or burden to the safety of the subjects compared to normal clinical practice in any Member State concerned. With regard to the informed consent requirements, the regulation authorizes investigators to obtain informed consent by 'simplified means' in the case of cluster trials involving only minimal risk, when the investigational medicinal products are authorized and used in accordance with the terms of the marketing authorization.

The French legislature enacted in 2012 a new Law on Research involving human subjects, commonly referred to as the Jardé law (Jardé law, n.d.). One of the major purposes of this law was to facilitate all biomedical research – including research on usual care – that involves only minimal risk for patients. It is important to recall that the French Parliament had already established in 2004 a minimal risk research category, under the name of 'research on usual care.' However, these provisions were never fully enforced, as the legal concept of 'research on usual care' was not properly defined. In addition, it was difficult for researchers to provide the evidence required for qualifying an intervention as usual care intervention (Matei et al., 2011). As a consequence, ethics committees were reluctant to authorize such clinical research. Most often these protocols were qualified as experimental research. Subsequently, the Jardé law is intended to match regulatory provisions to the risks posed to participants by research interventions. Accordingly, three categories of research have been identified according to the level of risks involved by research interventions: (1) interventional research involving higher than minimal risk, (2) interventional research involving minimal risk (covers only research on nonmedicinal products), and (3) noninterventional research. The law establishes specific provisions for the research category that involves only minimal risk for human subjects. In particular, only the review by an ethics committee is required, without authorization by the competent authority, and consent may be given orally.

The move toward a risk-adapted regulatory approach raises further key theoretical and practical issues that need to be addressed at both national and international levels. The defenders of learning health care models have already underlined one of these issues: how to draw the line between 'usual care' and 'research' under the risk-based approach. For example, the Jardé law defines interventional research as studies involving interventions *not justified by the person's usual care.* However, the line between 'usual care' and 'research activities' is often hard to discern. Another major question is the lack of definition of minimal risk. In France, the new law does not define the 'minimal risk.' The lack of legal definition will be overcome by the publication of a detailed list of interventions involving only minimal risk (such as blood sampling, external monitoring of blood pressure, EKG, etc.). This list will be established on empirical evidence. Similarly, the European regulation does not provide a definition of 'low intervention.' Instead, the difficulty has been circumvented by limiting the low intervention category to research on approved medicines, within and without their marketing authorization (and in this latter case, only when their use is evidenced based). The underlying assumption is that the existing knowledge and prior experience with the tested medicinal product prevents any unknown risk, which can be subject to debate.

To sum up, the recent advances in clinical research call for a radical change in attitudes toward therapeutic effectiveness assessment, based on stronger involvement of the participants and their families, translation of new information into medical evidence, and networks of shared clinical and research data (Navathe and Conway, 2010). The risk-based approach as a legal and regulatory solution to the legal issues raised by these changes in clinical research has its limitations. For instance, issues related to data protection legislation or intellectual property rights generated by the use of large health databases are only partially addressed. Also the involvement of patients in the assessment of clinical effectiveness has important implications in terms of responsibility and liability. Even though the regulatory risk-based approach neither addresses nor solves all the issues surrounding the contemporary development of research on therapeutic effectiveness, the enforcement of these regulations will permit us to appreciate its impact on these new approaches.

Therapist–Patient Relationship

Paul Crits-Christoph, University of Pennsylvania, Philadelphia, PA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The therapist–patient relationship is accepted widely as a central aspect of psychotherapy. This article will examine the varying perspectives on the therapist–patient relationship in both historical writings on psychotherapy and in current research and theory. Methodological issues relevant to studies attempting to investigate the therapist–patient relationship will also be delineated, and speculations on future directions for research and theory will be offered. But, the first section will attempt to define the therapist–patient relationship.

Definition of the Therapist–Patient Relationship

A 'relationship' is something that emerges when two or more people interact. However, with the therapeutic relationship, and perhaps any human relationship, it becomes difficult to think about or observe this 'emergent' property of the interaction independent of the contributions of each of the participants. The thoughts, feelings, attitudes, and behaviors of each of the participants, as well as the technical interventions of the therapist, all potentially play a role in the formation and maintenance of the therapist–patient relationship and need to be considered in any conceptualization of this facet of psychotherapy. In the broadest sense, then, the therapist–patient relationship is the emergent entity that is produced by the expectations, attitudes, thoughts, feelings of the participants about each other, as well as their behaviors toward each other.

Despite this broad and elusive definition of the construct, we know a good therapist–patient relationship, and a bad one, when we see it. A good therapist–patient relationship is usually evident when patient and therapist are acting in a warm, caring, empathic, and productive way toward each other. A bad therapist–patient relationship is characterized by distance, hostility, lack of respect, manipulation, or poor capacity to work effectively together.

As mentioned, the positive, 'reality'-based aspects of the therapist–patient relationship are subsumed under the concept of the 'therapeutic alliance.' Bordin's (1979) definition of the therapeutic alliance in particular has had considerable influence in theoretical and research writings. The therapeutic alliance, according to Bordin (1979), consists of three elements: (1) agreement between patient and therapist on the goals of therapy, (2) agreement on the tasks of therapy, and (3) the affective bond between patient and therapist. Although the bond incorporates the emotional aspects of the patient–therapist attachment, agreement on goals and tasks refers to expectations or cognitive elements of the relationship. To understand how these aspects of the therapist–patient relationship have come to be accepted widely and how they apply to the full range of different psychotherapies requires a historical perspective, given in the next section.

History of Concepts of the Therapist–Patient Relationship

Modern views of the therapist–patient relationship can be traced directly to Freud's writings. Freud considered the therapist–patient relationship to be a unique laboratory for observing aspects of patient's personalities that may have relevance to the patient's symptoms or psychopathology. Moreover, he utilized the relationship to effect change in the patient (*see* Psychoanalysis in Clinical Psychology). Freud described several components of the therapist–patient relationship. In terms of the patient's contributions to the relationship, Freud (1958) described both positive and negative transference reactions. Transference refers to the expectations, desires, thoughts, and feelings that are 'transferred' from a previous relationship on to a new relationship (e.g., the therapist). Positive transference was further divided into the reality-based "friendly and affectionate aspects of the transference which are admissible to consciousness and which are the vehicle of success" (Freud, 1958) vs other positive feelings and perceptions (e.g., sexual feelings, strong dependency) that were not reality-based, originating instead from the patient's unconscious linking of the therapist with significant past relationships. Similarly, negative transference included negative feelings and perceptions that originated from past relationships and were not evident in the therapist–patient relationship. Finally, Freud acknowledged that distortions in the therapist–patient relationship might result from the therapist unconsciously linking the patient to significant people in the therapist's past ('countertransference') (*see* Transference in Classical, Contemporary, and Cultural Contexts). Although reality-based friendly feelings motivated a patient to stay in treatment and engage in therapeutic work, distorted positive and negative transference reactions served as the basis for the therapist's technical interventions. By illustrating these distortions to the patient, previously unconscious conflicts are brought to the conscious level and such insights lead to patient improvements.

A number of subsequent psychodynamic theorists expanded upon Freud's discussion of the therapeutic relationship. The term 'ego alliance' was used by Sterba (1934) to refer to the patient's capacity to work with the therapist in treatment,

alternating between experiencing and observing. Subsequently, Greenson (1965) described this capacity as the 'working alliance,' and theorized that it stemmed from the patient's mature ego functioning in conjunction with identification with the work orientation of the therapist. Zetzel (1956) discussed the patient's attachment to the therapist (labeling it the 'therapeutic alliance'), and postulated that it originated from positive aspects of the mother–child relationship.

Because the analysis of transference became the defining feature of many approaches to psychodynamically oriented psychotherapy, a relatively large clinical literature has developed on this aspect of the therapist–patient relationship. Esman (1990) has collected a sample of influential papers on transference that illustrates the perspectives of a range of psychoanalytic writers including Freud, Klein, Winnicott, Gill, Kohut, Kernberg, Lacan, and others.

Although there are historical disagreements about whether the positive aspects of the therapist–patient relationship represent patient distortions or realistic appraisals of the treatment situation, the writings of Bordin (1979) served to mark the beginning of consensus on the importance of the reality-based, collaborative therapist–patient relationship (the 'alliance'). This is not to say that other schools of psychotherapy had been silent on the importance of the therapist–patient relationship. In many ways, client-centered psychotherapy, developed by Rogers (1951), can be seen as an approach that relied exclusively on a positive therapist–patient relationship for inducing change. Unlike the psychodynamic emphasis on reactions of the patient to the therapist, Rogers' (1951) focus was on the therapist's contribution to the relationship. Rogers claimed that if certain 'facilitative conditions' (therapist empathy, genuineness, and unconditional positive regard) were provided to a patient, the patient's natural tendencies for growth and healing would be activated.

The behavioral school of psychotherapy, however, has often been characterized as minimizing the role of the therapist–patient relationship. This school of therapy describes behavior change in terms of principles of learning (i.e., classical or operant conditioning; social learning theory), with no focus on the context in which therapy takes place – i.e., the therapist–patient relationship. Practicing behavior therapists came to realize that this was an oversimplification. Goldfried and Davison (1976), for example, devoted an entire chapter of their book on clinical behavior therapy to the therapist–patient relationship, describing how behavior therapists can use the therapeutic relationship to directly sample aspects of the patient's problematic behavior. Moreover, a positive relationship was seen as crucial to facilitating favorable patient expectations for change and receptiveness to the behavioral approach, enlisting patient's active cooperation in treatment, and motivating the patient to attempt new behaviors outside of therapy.

Beck's cognitive therapy approach has long acknowledged that the therapist–patient relationship was important to successful outcome, but it was largely considered a 'given,' with only brief explicit attention to the relationship in the original writings on cognitive therapy as a treatment for depression (Beck et al., 1979). However, as cognitive therapy expanded its scope to the treatment of other disorders, especially personality disorders, the therapist–patient relationship has come into focus increasingly as a key element of the process of treatment (Newman, 1998).

Emphases in Current Theory

Different schools of psychotherapy have largely converged in their agreement that the therapist–patient relationship is of central importance to successful psychotherapy. Even psychodynamic approaches to treatment, which historically have focused attention on patient distortions about the therapist, now highlight the role of the reality-based aspects of the therapist–patient relationship. The consensus about the importance of the therapeutic alliance is evident in an edited volume by Safran and Muran (1998) presenting chapters examining the alliance in psychodynamic, cognitive, experiential, strategic, family, and group psychotherapies.

Safran and Muran (1998) have identified a number of principles on which there is basic agreement across therapeutic schools regarding what the therapist can do to facilitate a positive alliance. Among others, these include establishing a bond with the patient by conveying warmth, respect, and interest, outlining the tasks and goals of treatment at the beginning of therapy, focusing on realistic goals, maintaining a clear therapeutic focus, keeping a balance between being active (which helps maintain the treatment focus and the patient's involvement) vs receptive to patient needs and experiences, and addressing ruptures in the alliances when they occur.

Despite the agreement that has emerged regarding the importance of the alliance, there remains considerable disagreement about how a positive alliance results in more favorable treatment outcome. One view is that the alliance in itself is curative (e.g., Rogers, 1951; Luborsky, 1984). This perspective proposes that a positive relationship between therapist and patient provides a corrective emotional experience for the patient. Through their relationship with the therapist, the patient emotionally learns over time that other people are not abusive, controlling, manipulative, or otherwise destructive in relationships, as the patient has experienced others to be in the past. Thus, the patient's core expectations or beliefs about people change, and this improves relationships outside of therapy.

The second view on the role of the therapist–patient relationship posits that a good alliance sets the stage for psychotherapy techniques to have their impact (e.g., Beck et al., 1979). Whether the techniques are cognitive behavioral, such as homework assignments, or psychodynamic, such as interpretations of interpersonal patterns, the patient's receptivity to such therapist techniques will depend upon the extent to which the patient has a good bond with the therapist and basically agrees with the therapist on the goals and tasks of therapy. In this model, it is neither a good relationship nor good techniques that lead to better outcome, but rather the interaction of the two – a combination of good techniques in the context of a good relationship.

Both of the above models assume that the alliance is a relatively stable aspect of the therapist–patient relationship.

A contrasting perspective has been offered that views the alliance as a relatively fluid process with ongoing ruptures occurring frequently during treatment sessions (Safran et al., 2011). It is unclear at this point whether such moment-to-moment fluctuations in the alliance are the norm or whether they occur primarily in the treatments of certain types of patients (e.g., those with severe problems in interpersonal relationships).

Research on the Therapist–Patient Relationship

Beginning in the 1970s, a variety of studies reported on the development of scales for assessing the alliance and examined its relation to psychotherapy outcome. Several reliable self-report measures and observer ratings scales (applied to tapes of psychotherapy sessions) were constructed. Many of the scales are linked to the theoretical model described by Bordin (1979).

Horvath et al. (2011) have summarized the literature on the relation of the alliance to psychotherapy outcome. In a metaanalysis of 190 independent data sources covering more than 14 000 treatments, these authors reported that, on average, there was a small-to-moderate relationship between the quality of the alliance during treatment and eventual treatment outcome. The alliance has even been found to be associated with positive outcome in studies of psychosocial treatments for children/adolescents (e.g., Kazdin et al., 2005) and elderly adults (Gaston et al., 1998). Moreover, the alliance was found by Horvath et al. (2011) to be related to treatment outcome across diverse psychotherapies. The size of the statistical relationship, however, suggests that the alliance is not the only factor in determining psychotherapy outcome. In brief, while the therapist–patient relationship appears critical, there is no reason to suggest that a good therapist–patient relationship is the only curative factor in psychotherapy.

Several studies have examined the common clinical hypotheses that good psychotherapeutic technique has its greatest impact in the context of a positive alliance, i.e., the alliance and technique interact to produce better outcomes. No consistent findings, however, have emerged across studies, with some investigations reporting evidence for an interaction (Owen and Hilsenroth, 2011), other studies yielding inconclusive but suggestive findings with small samples (Gaston et al., 1998), and some work suggesting that any interaction between techniques and alliance depends upon characteristics of the patient, particularly the patient's typical level of interpersonal functioning (Høglend et al., 2011).

Methodological Issues in Research

A host of methodological issues need to be considered when conducting research on the relation of the alliance to treatment outcome. Perhaps the most crucial issue relates to whether a positive alliance is actually a causal factor in producing better treatment outcomes. The reverse causal direction needs to be entertained as well: as symptoms improve, patients are more likely to report a positive attitude about the therapist and treatment. Thus, significant correlations between the alliance (measured during treatment) and outcome may be spurious – early improvement in symptom lead to both a positive alliance and good eventual treatment outcome. This potential confounding between the alliance and prior improvement has now been evaluated in 11 different studies (reviewed in Crits-Christoph et al., 2013). On average across studies, there is evidence that the alliance remains moderately associated with treatment outcome even when prior improvement was controlled; however, substantial variability in this effect across studies is apparent. Thus, this important issue of the direction of causality remains to be addressed in future research.

Another methodological issue of importance is the fact that psychotherapy is a dyad consisting of a patient and a therapist, with either (or both) potentially contributing to a particular process. It may be, for example, that the connection between the alliance and treatment outcome has more to do with differences among therapists in their abilities to form positive relationship with patients and less to do with differences among patients in their capacity to form a positive patient–therapist relationship. Modern statistical techniques such as multilevel modeling have permitted studies to decompose the alliance–outcome association into the component that is related to differences among therapists and the component that is related to differences among patients. To date, the evidence indicates that it is indeed the differences between therapists, not patients, that are most responsible for the association between the alliance and outcome (Baldwin et al., 2007; Crits-Christoph et al., 2009). A further consideration is that most research linking the alliance to treatment outcome has examined the alliance in only one or two sessions of psychotherapy (usually early in treatment sessions). But if the alliance varies from session to session depending on ruptures in the alliance triggered by events occurring inside, or outside, the therapeutic relationship, it may be necessary to measure the alliance over many sessions to characterize the patient–therapist relationship as generally 'good' or 'poor.' Indeed, a recent study demonstrated that the relation between the alliance and treatment outcome increases substantially as the alliance is measured in progressively more sessions, with at least four sessions needed to adequately capture the general quality of the alliance for a psychotherapy treatment as a whole (Crits-Christoph et al., 2011).

Future Directions

The almost universal acceptance of the therapeutic alliance as an essential part of psychotherapy points the way to some obvious future directions for scientific study. If a positive therapist–patient relationship is key to successful outcome, and the therapist contribution to the alliance is what explains the connection between the alliance and outcome, can therapists be trained to maximize the quality of the alliance? If not, is this because good therapists are 'born' not 'made'? Resolution of this issue could have profound implications for the training of psychotherapists. If therapists cannot be taught how to establish and maintain a good alliance, perhaps greater effort should

be placed on the selection process for training programs in the disciplines (psychology, psychiatry, social work) which conduct psychotherapy. Priority would be given to applicants who have innate interpersonal skills (e.g., empathy) that are associated with positive therapist–patient relationships. If, however, therapists can be trained to maximize the quality of the alliance, such training should become a core element of all training programs, regardless of which treatment modalities are emphasized.

Rather than focusing on the broad question of whether the alliance predicts treatment outcome, future research is likely to continue to explore more refined and specific questions that attempt to unravel the contexts under which a positive alliance is especially important. Larger and more definitive studies, following up on intriguing preliminary findings with smaller samples, can identify the treatment variables and patient dispositional variables that interact with the therapeutic alliance to produce optimal outcome. Research on human relationships, emerging from basic studies in social cognition and interpersonal processes, is likely to provide direction for understanding the nuances of the therapist–patient relationship. Similarly, as intensive empirical examination of the therapist–patient relationship increases our knowledge about the influence of this relationship, we may find applications of these findings to other helping relationships in medicine and elsewhere in society.

Thick Description: Methodology

Tanya M Luhrmann, Stanford University, Stanford, CA, USA

Abstract

'Thick description' is the term that Geertz used to describe ethnography in one of the most famous and influential anthropology texts in the second half of the twentieth century, *The Interpretation of Cultures* (1973). It has come to imply two different things: on the one hand, good ethnography – what all anthropologists have done and do when they write up the results of solid, careful ethnography – and, on the other hand, what Geertz understood to be the intellectual entailments of this particular methodology.

'Thick description' is the term that Geertz used to describe ethnography in one of the most famous and influential anthropology texts in the second half of the twentieth century, *The Interpretation of Cultures* (1973). The phrase was the title of the first essay in the volume of the collected essays, and Geertz explained at the time that he had written it to state his theoretical position as generally as he could. As a result, thick description has come to imply two different things: on the one hand, good ethnography – what all anthropologists have done and do when they write up the results of solid, careful ethnography – and, on the other hand, what Geertz understood to be the intellectual entailments of this particular methodology.

As Methodology

Geertz borrowed the phrase 'thick description' from the philosopher Ryle (1949), who used it to contrast two different ways of describing the same piece of behavior. Ryle's example was a boy's twitch and his wink. Both could be described as 'rapidly contracting his right eyelids.' That kind of description Ryle called 'thin.' He used the term 'thick description' to characterize the intentional, communicative, interpretative, meaning of the behavior: why it was done, how it was read, and using which social codes. That, Geertz argued, was the object of ethnography, "a stratified hierarchy of meaningful structures in terms of which twitches, winks, fake-winks, parody, rehearsals of parodies are produced, perceived and interpreted, and without which they would not … in fact exist, no matter what anyone did or didn't do with his eyelids" (1973, p. 7).

Ethnography is the written description of long-term participant observation. Professional anthropologists now typically expect that a person doing serious fieldwork (of the sort required for an anthropological dissertation, for example) will spend at least a year living in the 'field,' in the social setting that they have chosen to study. They expect that fieldworkers will speak the dominant language spoken in that setting, and they expect that fieldworkers will learn about that world not only or even primarily by interviewing its members, but also by learning how to participate as a member themselves: how to joke, to be in relationship, to be an appropriate person of their type (e.g., a woman in her 20s) in this social setting. If you are studying Londoners who practice witchcraft and magic, you learn how to write rituals, to read tarot cards, and to feel the magic running in your blood. If you study Malagasy villagers who plant rice and perform cattle sacrifice, you work in the rice paddies and offer up a cow. Particularly in recent decades, professional anthropologists have decried their pith-helmeted, informant-paying forebears. They are likely to evaluate the student fieldworker by asking whether the student hung back from human contact or really got to know the people he or she worked among and came to be accepted by them. The point of this emphasis is to make sure that the fieldworker has grasped the realities and the rules of engagement of the world he or she has come to study. As Stephen Hugh-Jones once remarked, there is little point of having an abstract debate about what it means when the natives say that they 'see' their gods during rituals if you have not participated in those rituals and learned that they involve hallucinogens.

Professional ethnographers use at least three criteria to help them judge the reliability and validity of the ethnographic report.

First, they look at the richness of observational detail. Ethnography can be at risk of being dismissed as hearsay or anecdotal. But when the observational detail, reliably reported, is detailed enough – 'thick' enough – these objections no longer seem plausible. Ethnographic monographs are often quite lengthy for that reason: the ethnographer supports an argument on a foundation of thousands of specific observations about thousands of specific events.

Second, they look for external corroboration of the ethnography. In part, this is provided by prepublication peer review by experts in the specific area of the world the ethnography concerns. However, the primary responsibility for external corroboration lies with the ethnographer, who is expected to refer to published materials by field subjects (when relevant) and by other ethnographers to support his or her conclusions. At this point in world history, there are few societies remote enough to be completely unknown.

Third, they look for evidence that the ethnographer knows the ethnographic area well. As in any discipline, the conventions to judge competence are somewhat arbitrary, but still powerful. A year of full-time fieldwork is considered minimal; more years provide more reassurance about the quality of the data. Ethnographies thus present the specific dates and conditions of the fieldwork. To be able to converse in the language is minimal; to command idioms, whether in the spoken language itself or in the metaphorical language of local practice, again provides more reassurance. Ethnographies should display mastery of the local idioms of practice (the intricacies of the sheep trade, for instance). To be accepted in the target social world well enough to have conversational and observation

access to field subjects is also minimal, and so ethnographies typically describe how that access was acquired and maintained; sometimes these accounts are called 'arrival stories.'

There is, however, a hard-to-specify distinction between the competent ethnography and the really good one. Ethnographies do much more than give an account of who did what and when. An ethnographer can sit in a courtyard for one full day and describe exactly what he sees, and his observations will fill a monograph, and the monograph will be unreadable and unintelligible. By contrast, good ethnographies are accounts of a social world that make sense of that world to those who are alien to it. "What the ethnographer is in fact faced with," Geertz explained, "is a multiplicity of complex conceptual structures, many of them superimposed upon or knitted into one another, which are at once strange, irregular, and inexplicit, and which he must contrive somehow first to grasp and then to render" (1973, p. 10). Good ethnography describes what is really important to understand about this world, both to the participants and to its observers; it conveys what people mean when they say, 'you really get it.' When anthropologists use the phrase 'thick description' to refer to the ethnographic method, they mean to imply that the anthropologist does serious, engaged fieldwork; that he really grasps the social process of the world being studied; and that he writes an ethnography so detailed and so observant that it is utterly persuasive.

As an Epistemology

"If you want to understand what a science is," Geertz remarks early on in his famous essay, "you should look in the first instance not at its theories or its findings, and certainly not at what its apologists say about it; you should look at what the practitioners of it do" (1973, p. 5). Ethnographers immerse themselves in another society for long periods of time, and collect far more bits of information than they could ever report or code or convey. Then they write books that attempt to describe the foreignness of that other world in ways that make it comprehensible to their readers.

As a consequence, Geertz argued, ethnographies are by their nature interpretations. They are not hypothesis driven and predictive. This does not mean that they are unconstrained and undisciplined. "That is like saying that as a perfectly aseptic environment is impossible, one might as well conduct surgery in a sewer" (1973, p. 30). But they are not normal science – normal social science – in the style of psychological experiments and economics theories. The anthropologist, from this perspective, is more like a literary critic who writes about a novel that anyone could in principle read. They may write about the novel in many ways – explain it to those who do not understand, praise or critique it, argue that other readers have misunderstood it, suggest that it captures certain human experiences that help its readers to see those experiences differently from before, and insist that one way of thinking about it is more illuminating than another. But whatever they do, that novel exists as an art form independent of their presence, and their job is to help others to appreciate it more deeply. The claim to attention of an ethnographic account does not rest on its author's ability to capture primitive facts in faraway places and carry them home like a mask or a carving, but on the degree to which he is able to clarify what goes on in these places, to reduce the puzzlement – what manner of men are these? – to which unfamiliar acts emerging out of unknown backgrounds naturally arise (1973, p. 16).

What can be interpreted, however, is only what can be 'read.' The power in the comparison of ethnography and literary criticism lay not only in the reasonableness of the general claim – fieldwork is indeed different from laboratory science – but in the pragmatic usefulness of its central metaphor. Following Paul Ricouer, Geertz not only compared the anthropologist to a literary critic, but described culture and social interaction as a text – the metaphorical 'literature' that the anthropological critic interpreted. More loosely, he described culture as discourse and as language. He argued that culture – "this acted document" (1973, p. 10) – was public because meaning was public. As an ethnographer, a watcher of others, you have no access to people's minds. What you can see is that they communicate, and you can interpret what they communicate, and what you are after is in effect the language or discourse that they are using, not the ideas they have in their mind. Geertz used Wittgenstein's private language argument to support the claim that culture, like language, was a public, social phenomenon, but his primary concern at the time was that you did not need to understand psychological process in order to be a good ethnographer. Understanding the mind was a psychologist's job; understanding culture was the anthropologist's.

This central metaphor, of culture as a text, gave the ethnographer something specific to do: to identify symbols that somehow represented the particular social process of that group, and to then explain their meaning. In a much quoted definition Geertz stated, "Believing, with Max Weber, that man is an animal suspended in webs of significance he himself has spun, I take culture to be those webs, and the analysis of it to be therefore not an experimental science in search of law but an interpretive one in search of meaning" (1973, p. 5). Geertz went on to argue that the kinds of things that anthropologists interpret – rituals, myths, cockfights – are themselves interpretations of the society in which they were found, and so the anthropologist is producing second- and third-order interpretations for a different purpose. "The culture of a people is an ensemble of texts, themselves ensembles, which the anthropologist strains to read over the shoulders of those to whom they properly belong" (1973, p. 452).

Because (from this perspective) culture is a semiotic system, so that all representation is in effect interdependent, and because the social behaviors that despite everything anthropologists tended to think of as cultural – rituals, stories, songs; the noninstrumental side of life – are also understood as interpretations of their own society, the anthropologist could focus on some practice that on the surface seemed trivial or irrational, and use that practice to understand and reflect upon the nature of the social whole. Geertz did this most famously in his essay on the Balinese cockfight. The cockfight is a seeming unimportant and irrational piece of Balinese culture in which grown men bet money they cannot afford to watch birds kick each other to death in illegal matches. Geertz suggested that Balinese men were gripped by their cockfights because the matches flung away the restrained, polished, social hierarchy

that otherwise defined Balinese daily life, and through his discussion, this small social practice became the prism through which you came to understand fundamental features of Balinese society.

In the decade after these two essays on thick description and the cockfight were published, Geertz became one of the leading figures of sociocultural anthropology, if not its dominant presence, and his work precipitated a paradigm shift in the field and influenced other fields as well, most notably history. The new approach was called 'symbolic' anthropology and contrasted both with functionalism (a primarily British approach which sought to understand how all elements of social practice contributed to the effective functioning of that social world) and structuralism (an initially French approach that sought to identify the formal logic underlying cultural representation). David Schneider and the midcareer Marshal Sahlins were also associated with this new emphasis on the way cultural practices represented social process, and symbolic anthropology tended to be associated with the department of anthropology at the University of Chicago, where Geertz had been before he left for the Institute of Advanced Study at Princeton. Rosaldo's *Knowledge and Passion* (1980), an ethnography that explores the society of the Filipino Ilongot headhunters through a dominant emotion term, is a good representative of symbolic anthropology.

Now, however, the phrase that is associated with thick description is 'interpretive anthropology.' That phrase tends to mean that the ethnographer values serious (in depth, detailed) fieldwork and understands the ethnography as an attempt to make the foreign world comprehensible to the reader. The phrase also often implies that the anthropologist is self-consciously aware of the literary nature of the ethnographic enterprise: that ethnography is an act of writing, and that successful anthropologists are first and foremost writers. Finally, the phrase often (but not always) implies that this writerly, interpretive act is the primary goal of ethnography, and that anthropology cannot be a hypothesis-testing science, because its methods will not allow it to be so. As a result, the phrase is sometimes used to imply more about what ethnography is not, than about what it is, and the phrase can be used as a battle cry by those who wish to see anthropology associated with the humanities. Those battles, however, take the phrase beyond the domain that Geertz first mapped out.

Think Tanks

Abstract

Think tanks first proliferated in Anglo-American countries during the mid-twentieth century but by the twenty-first century had become prevalent throughout the world. These organizations vary dramatically in size, legal status, policy concerns, and organizational structure but share a mission to inform policy, educate political elites, and shape decisions. The political influence and social impact of policy institutes waxes and wanes across time and policy issue, as well as from one political culture to the next. They have become key informants to policy making at local, national, and transnational levels of governance.

With the label 'brain trust' or 'policy institute,' the idea of what constitutes a 'think tank' has changed dramatically since the last century. The term 'think tank' originated in the United States during World War II. It was used to describe secure and 'sealed environments' for expert strategists preoccupied with military planning, most notably the RAND Corporation. By the 1960s, the term was entrenched in the lexicon and was being applied to independent policy research institutes throughout the English-speaking world.

Think Tank Diversity and the Dilemmas of Definition

During the twentieth century, social science definitions of think tanks were shaped by Anglo-American experience. The proliferation of think tanks was most pronounced in the United States and remains so. In this country, generous foundation and corporate support, as well as extensive government contracting out of research boosted their development. The constitutional architecture, federal structure, and relatively weak party system provided a conducive environment for well over 1500 think tanks to engage in policy debates and interact with government (Weidenbaum, 2011). By contrast, the stronger party systems, corporatist modes of decision making, strong, and relatively closed bureaucracies, and sometimes weak philanthropic sectors are considered to have dampened think tank development in the parliamentary systems of Great Britain, its former dominions of Canada, Australia, and New Zealand, and most of Western Europe (Stone, 1996). Nevertheless, think tanks were present in these systems throughout the last century although in considerably smaller number and size than their US counterparts.

The degree of legal, financial, and intellectual autonomy and independence differs substantially from one nation to another; a sociopolitical context that inevitably shapes the channels for, and modalities of, communicating research and analysis on contemporary issues. Think tanks are (usually) relatively autonomous from government, political parties, and pressure groups as well as business although they are often in resource-dependent relationships with these patrons. Nevertheless, institutes attempt to maintain their research freedom and usually claim not to be beholden to specific interests. Think tanks seek policy influence primarily through intellectual argument and policy analysis rather than direct lobbying; they are concerned with the development and application of ideas and concepts that underpin policy, although not all their research and activity need be policy relevant. Think tanks collect, synthesize, and create a range of information products, often directed toward a political or bureaucratic audience, but also for the benefit of the media, civil society groups, and the general public. They are concerned with knowledge creation although political communication and effective knowledge utilization may be their primary purpose.

Think tanks defy exact definition. In both the scholarly and professional field of governance, think tanks can be defined as policy research centers engaged in policy analysis and advocacy that is directed toward government but also undertaken for international organizations, the business and nonprofit sectors. Think tanks vary considerably in size, legal form, policy ambit, longevity, organizational structure, standards of inquiry, and political significance. Not only is there considerable scholarly difference over how to identify these organizations, but the directors and senior scholars of these organizations often make subtle distinctions between 'research institute' and 'think tank.' Such disputes usually revolve around the role of advocacy on the one hand, and organizational capacity for high-quality policy research on the other, with think tanks deemed to do the former and research institutes the latter. Often, this distinction is false and points to a deeper ontological distinction made between 'knowledge and power.' Generally, think tanks are represented as a bridging institution, linking the scholarly world and the separate political domain by translating jargon ridden, densely technical or highly theoretical research into policy palatable recommendations. As a UNDP (2003: p. 6) publication put it: "They are the bridge between knowledge and power in modern democracies."

Some organizations claim to adopt a 'scientific' or technical approach to social and economic problems; others are overtly partisan or ideologically motivated. While some institutes are routinely engaged in intellectual brokerage and the marketing of ideas, whether in simplified policy-relevant form or in sound bites for the media, others are more academic. Many institutes are discipline-based – economic policy think tanks, foreign policy institutes, and social policy units. Specialized environmental think tanks, regionally focused operations, and those that reflect the communal interests of ethnic groups appeared

from the 1990s. While most display a high level of social scientific expertise or familiarity with governmental structures and processes, there is considerable diversity in style and output of think tanks. The intellectually engaged 'ink tank' can be poised against the action-oriented 'think-and-do tank': that is, there are significant differences between think tanks that are scholarly in focus and geared toward publication of books and reports, and think tanks that are more activist and engage in grassroots activity. However, the impact of information technology has leveled the playing field somewhat, as all think tanks are heavily engaged in sophisticated Web site development as well as forms of social networking for targeted dissemination of output. As a consequence, a sound reputation for quality research and analysis, and credibility in political and policy communities, while intangible, has increasingly become the standard of success.

The Western view that a think tank requires independence and autonomy from the state, corporate, or other interests in order to be free-thinking and proffer dispassionate or nonpartisan policy advice does not accord with experiences in other cultures. In many nation states, the line between policy intellectuals and the state is blurred to such an extent that to talk of independence as a defining characteristic of think tanks makes little sense. Many organizations now called think tanks operate within government; this is evident in China (Zhu, 2011). Elsewhere, some institutes have been founded or incubated in government and subsequently 'spun off' as independent entities; it is not unusual to find institutes with political patrons or formal links to political parties. Many of the German political foundations, for instance, have been established by political parties or have strong ties to the Länder and some German institutes have grown to such a large size that they rival some of the major American institutes. In other circumstances, research institutes are attached to corporations, as is evident in Japan, South Korea, and Taiwan. Notwithstanding funding dependence or their political affiliation, high-quality research and analysis along with critical advice is feasible.

Accordingly, financial independence can be construed as developing an endowment or having numerous sponsors and a diverse funding base, so that an organization is not dependent on any one benefactor. Scholarly independence is reliant upon certain norms and practices within an institute: the processes of peer review and a commitment to open inquiry rather than directed research along with the willingness of directors to protect and champion such norms. Legal or administrative independence comes from constitution as a private organization. Administrative and financial independence may be a facade under authoritarian or illiberal regimes where censorship and control prevail. Alternatively, some institutes may exhibit a high degree of research freedom despite being found within the state architecture. Appreciation of the political culture of a nation is essential to interpreting think tank independence and intellectual leverage.

A further problem of definition is that it is often difficult to establish a precise distinction between think tanks and other organizations with similar objectives, for example, operating foundations. Think tanks could also be regarded as more intellectual variants of pressure groups or nongovernmental organizations (NGOs): Many now base their arguments on relatively sophisticated research that is sometimes conducted in-house. Nevertheless, there are important differences: think tanks do not engage in public demonstrations and they tend to address multiple policy areas (notwithstanding specialization) rather than focus on a single issue as do many pressure groups. There are similarities with consultancy firms, financial institutions, or legal offices that provide contract research and analysis, although these organizations engage in a wider range of activity than research; yet many think tanks only survive through their consultancy services and contract research. Some think tanks have been described as 'universities without students' (Weaver, 1989: p. 564). While the relationship between think tanks and universities has been close in most political systems, the vast majority of think tanks are not degree-granting institutions. There are a few exceptions, however, notably RAND in the United States and FLACSO in Latin America. In terms of future think tank development, the blurring of boundaries and the overlap of objectives and activities between institutes and other organizations in our 'knowledge societies' may mean that these organizations lose organizational distinctiveness and their monopoly on the claim that they 'bridge' science and the state.

Worldwide Expansion and Transnational Networking

In the last two decades of the twentieth century, the number of think tanks proliferated. Estimates vary along the lines of definition, but 5000 think tanks worldwide is not an unrealistic figure (McGann and Sabatini, 2011). Countries where think tanks were already present such as the United States, Britain, Sweden, Canada, Japan, Austria, and Germany witnessed further organizational growth. Increased competition in the think tank industry has often encouraged policy advocacy and the politicization of institutes, most particularly in the United States. The Heritage Foundation in Washington DC is usually cited as the exemplar but similar advocacy styles can be observed elsewhere. Democratic consolidation and economic development in Latin America, the Indian subcontinent, and Asia provided fertile conditions for think tank development, particularly as higher education systems expanded in these regions creating new generations of educated professionals and opinion leaders. The demise of the Soviet Union, the color revolutions, and the Arab Spring opened new political spaces for donor agencies and policy entrepreneurs to support think tanks as both a driver and a symptom of civil society capacity building (Stone and Maxwell, 2005).

On the one hand, the global think tank boom has been prompted by philanthropic foundations, corporations, and other nonstate actors demanding high-quality research, policy analysis, and ideological argumentation as advisory input within their organizations. On the other hand, growth has been propelled by grants, gifts, and other funding from governments and international organizations seeking to extend policy-analytic capacities or promote evidence-based policy formulation in developing and transition countries. Well-known programs include the 'Think Tank Initiative' supported by Hewlett Packard and administered by Canada's International Development Research Center, as well as the Open Society Foundation's Think Tank Fund that supports new institutes

across Central and South Eastern Europe and the southern Caucasus.

As a corollary, donor organizations often regard think tanks as NGOs and as entrepreneurs for the promotion of civil society development. Similarly, think tanks are often viewed by donors as an agent of democratization and a vehicle for public participation in policy debate. However, think tanks are an elite and relatively technocratic organizational expression of civil society when constituted as NGOs or other private forms of organization. The legitimacy for their input into policy making is claimed on the basis of their expert status and epistemic authority. This basis for policy engagement is in tension with rationales of think tank activity being a mode of democratic deliberation or representing a pluralistic counterweight to the state monopoly of decision making.

The think tank model has been exported around the world. The Anglo-American term and institutional template of 'think tank,' with all its cultural connotations, has penetrated the political systems of developing and transition countries. While the term is ubiquitous, its translation into organizational formats in quite different sociopolitical environments has been varied, taking hybrid form in countries as diverse as Vietnam or Croatia. After two and a half decades of transition, think tanks have occasionally come to be seen as an unwelcome foreign influence in some of the states of Southeastern Europe. Donor-funded think tanks sometimes supported uncritically many of the market liberal policy priorities emerging from the power centers of Brussels and Washington DC. Along with the high social costs of such programs, and in the wake of the Euro-crisis, the analytical support seen to be given by think tanks is one possible contributing factor to the rise of political populism in the region and increasing disdain for expert bodies. Even so, through other parts of Central and Eastern Europe as well as the former Soviet Union, think tank initiation remains a popular start-up option for young professionals.

International organizations such as the United Nations agencies, the World Bank, the International Monetary Fund, and the World Trade Organization have drawn think tanks into their ambit via conferences, joint research, and fellowship programs (for example, UNDP, 2003). The World Bank launched the Global Development Network (GDN) to promote think tanks in developing countries (Plehwe, 2007). The European Community provides yet another institutional forum for think tank activity with the emergence of EU-wide think tanks such as Notre Europe or the Centre for European Policy Studies seeking to transcend specific national identities with research and policy proposals for regional integration. Furthermore, with ongoing advances in information and communication technology, policy research disconnected from specific organizational settings has become increasingly feasible and fashionable. It has also made international research exchange and collaboration between think tanks commonplace.

Think tank transnationalization has been fuelled by the growth of global knowledge networks and this development can be seen as another manifestation of the 'bridging' function of think tanks (Stone and Maxwell, 2005). These networks have promoted transnational policy analysis and scientific expertise. They create the overlapping personal and communications infrastructure that allows the fast transfer of new ideas and policy learning across borders.

Networking ranges from the very informal, socializing or the 'thin' element of a virtual network through to formal international associations with a secretariat and large membership. Global and regional think tank networks like GDN and PASOS (a network of 30+ think tanks from the former Soviet Union and Central and Eastern Europe) have become extensive. International networks have coalesced around common areas of interest and policy themes as well as around ideology. For example, the Institute for European Environmental Policy has offices in London and Brussels and a network of partners throughout Europe. Tied by ideology, the Atlas Economic Research Foundation connects a global network of more than 400 free-market organizations in over 80 countries to the ideas and resources needed to advance the cause of liberty, providing start-up funds and technical assistance. Since 1997, the Japan Center for International Exchange has convened 'Global ThinkNet' meetings to promote policy-oriented dialogues within Asia and between Asia and other regions. Additionally, think tanks have become transnational by opening branch offices in other countries, as does RAND, the Carnegie Endowment for International Peace and the Urban Institute.

Networks have also become a form of governance. The typical target of the think tank has been government. In an era of privatization, contracting-out, and the entrenched logic of the 'new public management,' the growing importance of the private and voluntary sectors in the delivery of public goods and services has de-centered policy dialogue and service delivery away from the state. This is more pronounced above the nation state where international organizations, corporations, and large international NGOs promote global policy programs and public–private partnerships to deal with transnational policy problems. These governance networks above the nation state tend to be more weakly institutionalized than at the national level where sovereign power is clearly defined in administrative institutions and state agencies. The more fragmented and fluid transnational policy space provides numerous opportunities for think tanks individually and in coalition to proffer their policy analysis services.

Policy Impact and Influence

Following this extensive organizational growth, scholarly interest has expanded. Where discussion of think tanks was once limited almost exclusively to Anglo-American systems (Abelson, 2006; Weaver, 1989; Stone, 1996), interest has expanded to comparative political analysis of think tanks in other OECD nations (for example, Boucher et al., 2004) and beyond to developing or transition countries (inter alia Stone and Maxwell, 2005; UNDP, 2003). Wider disciplinary interest has emerged to include international relations and security studies specialists as well as a greater array of anthropologists, economists, and sociologists writing in this field.

Analysis of think tanks has diverged into two branches. Early research focused on the organizational form where writers were interested in explaining why and how think tanks have emerged and why some think tanks are influential. They distinguished independent public policy institutes from academic research centers, government research units, or

lobbyists. They focused on the organizational ingredients of what makes a think tank successful, how think tanks are managed, who funds them, who quotes them, and whom they try to influence (inter alia Struyk, 2007; Weaver, 1989; Weidenbaum, 2011). Initially, the growth and increasing diversity was represented as sign of a healthy pluralist democracy where think tanks contributed to a 'marketplace of ideas.' However, as competition for resources and policy attention became more acute in the 1980s, a new breed of ideologically aggressive think tank emerged in the United States, and emulated elsewhere, whereby policy partisanship lead observers to speak of a 'battlefield of ideas' with winners and losers in policy debate.

Writers in the second branch analyzed think tanks as a vehicle for broader questions about the policy process and the role of ideas and expertise in governance (inter alia Abelson, 2006; Campbell and Pedersen, 2011; the contributions in Stone and Maxwell, 2005). They employed network concepts such as 'policy community,' 'advocacy coalitions,' and 'epistemic communities' to explain why ideas matter. Others addressed think tank roles from a neo-Marxist or Gramscian perspective (Pautz, 2011; Plehwe, 2007) to argue that policy research is free neither of ideological content nor of material (class) interests. Yet others have utilized Bourdieu's field analysis (Medvetz, 2012) or adopted discourse frameworks (Fischer, 2003) to unveil the argumentative power of research and analysis and the capacity of ideas to shape public and policy maker perceptions of reality.

These studies cut to a central issue in the study of think tanks: Do think tanks exert policy influence, and if so, how? Notwithstanding their extensive growth, think tanks do not enjoy automatic political access or unhindered bureaucratic routes to decision makers. Think tanks need to have some kind of engagement with government if they are to have policy relevance; however, their desire to preserve intellectual autonomy means that most think tanks need to strike a delicate balance between dependence on government and political parties as clients, and isolation from such audiences that comes from policy research that is either too critical and uncompromising or too esoteric and irrelevant to pressing political timetables. Conducting policy-relevant research and attempting to broker it to decision makers does not equate with policy influence. This conundrum has been the major methodological problem in the study of think tanks.

Proof of influence is elusive. There is no clear causal nexus between policy research or an idea espoused by an institute, and political decisions and policy change. It is a rare occurrence that a policy outcome can be attributed to one organization, as there are numerous intermediary forces: political parties, interest groups, and the media also shape the content and reception of ideas. Furthermore, the cognitive order of politicians and bureaucrats cannot be accessed by 'think tank' researchers, and interviewing has its own problems of faded memories and selective recall in establishing the veracity of perceptions of think tank policy input. This hiatus is compounded as the political stature of many institutes waxes and wanes over time. Moreover, the criteria by which influence is assessed vary considerably.

Nevertheless, there are many countries where overstretched bureaucracies and limited capacities for in-house governmental policy analysis provide the opportunity for think tanks to serve government needs; however, the degree of incorporation and cooption varies from think tank to think tank and from one country to another. Latin American institutes, particularly the liberal institutes, were often marginal to the political system until the demise of authoritarian regimes. By contrast, a group of elite think tanks in Southeast Asia have enjoyed a much closer relationship with their governments where the trade-off was accommodation with government concerns and controls. The line between policy 'engagement' and 'entrapment' becomes unclear in such circumstances (Acharya, 2011). A large number of neoliberal or free-market research institutes eschew government funding in order to lay claim to untainted policy analysis. Their critics argue that such institutes can be beholden to other interests such as corporate donors. The organizational choices made by think tanks about their relationship to centers of power and authority must be understood not only by reference to the ideological disposition or mission of the think tank, but also by acknowledging environmental conditions such as legal and economic constraints of the political culture in which they are located.

Outside the political sphere and state sector, think tanks have cultivated other audiences. Students and academics in colleges and universities regularly use think tank publications. Foundation officials, business executives, bureaucrats from various international organizations, university researchers, journalists, and, for want of a better term, the 'educated public' are often engaged by think tank pursuits. Similarly, third-sector intellectuals such as are found among trade unionists, faith-based spokespeople, NGO leaders, and social movement activists can be attracted by the intellectual and ideological sustenance to be found in the think tank community. Indeed, think tanks have became more accessible to a wider range of publics via blogs, YouTube, and other media as they move into the social networking sphere 'twittering' their events and publications. As they do so, think tanks provide an organizational link and communication bridge between their different audiences. They connect disparate groups by providing a forum for the exchange of views, by translating academic or scientific research into policy-relevant 'sound bites,' and by spreading policy lessons internationally. Again, this is a pluralistic conception of a 'marketplace of ideas,' but one that allows a wider societal realm for understanding think tank impacts and influence.

Much of the preceding discussion has focused on individual think tanks seeking impact in short political time horizon or in medium-term policy planning. However, it may be more fruitful to think of influence in the longer term. Paradigmatic change usually occurs over generations. Rather than influence resting in the scientific work of one or more significant scholars, it rests in the aggregate contributions of the research community as whole, of which think tanks are just one type of knowledge actor. It is the collective weight and longer term structural impact of scientific consensus or orthodoxies that institutionally embed certain knowledge as dominant or hegemonic within international organizations, government programs, and other evolving architectures of governance or what has been described as a 'knowledge regime' (Campbell and Pedersen, 2011). The paradigmatic influence of knowledge in governance is much more incremental and 'atmospheric.' As John Maynard Keynes

(1936: p. 383) noted last century, knowledge can be rather more powerful and pervasive in the long term.

> The ideas of economists and political philosophers… are more powerful than is commonly understood. Indeed the world is ruled by little else. Practical men who believe themselves to be quite exempt from any intellectual influences, are usually the slaves of some defunct economist. Madmen in authority who hear voices in the air are distilling their frenzy from some academic scribbler of a few years back.

Yet, due to the passage of time and other intermediary factors, it is difficult methodologically to demonstrate, in positivist terms, ideational cause and subsequent governance effect.

This kind of long-term structural influence is different from the more mundane policy uses of knowledge agents on the one hand, and the symbolic or ritualistic use of knowledge artifacts for legitimacy in governance on the other. In short, the relevance of think tanks may be considered in terms of unintended consequences and negative impact. Rather than conceiving a one-way supply process of think tanks pushing policy knowledge, data, and analysis *into* government circles, it may be more pertinent to consider when, why, and how politicians and bureaucrats find these bodies useful. Rather than seeking sound advice for 'rational' policy making, the demand for think tank products and services can be much more instrumental. Think tanks represent an indirect form of legitimacy for the commissioning government department or international agency in having sought an 'evidence base' or scientific foundation for decisions. Think tanks also have symbolic value: state agencies can legitimize their policy position by arguing that they are consulting independent experts or civil society organizations. For instance, they are useful as 'independent' evaluators monitoring progress on adherence to legislation or international treaties and agreements.

They contribute to the 'everyday affairs' of governance and institution building by facilitating exchange between official and other private actors via networks as well as through various 'low-key' training and professional development courses many institutes offer to the public service. Other mundane roles include organizing seminars and hosting foreign delegations. Because of their professional image, they are viewed as more benign or cooperative partners when compared to the relatively more critical stance and occasionally disruptive lobbying of many NGOs. Think tank work can also be used as an ex post facto justification of policy that was decided upon without reference to independent sources outside government. Suggestions that think tanks are influential when their research is taken on board by government can by undermined if that research is politicized, especially when policy actors are dealing with sensitive social or economic issues. Via selective use, decontextualization, or misquotation, research findings are easy to abuse. Decision makers face incentives to do so to reinforce their policy positions (or prejudices). They will look to institutes that are generally supportive of their policy goals and ideology rather than engage in a time-consuming comprehensive search for the most reliable, 'scientific' or 'evidence-based' policy advice. Not all think tanks can be influential.

A recent development, and one that reflects think tank institutional embedding in the policy milieu, is the rise of support services for think tanks. A cottage industry of advisors and consultants has emerged providing tool kits and guide books or management expertise on how to manage a think tank (Struyk, 2007), how to network a think tank (Weyrauch, 2007), or how to engage in best-practice research (Buldioski, 2009). The Atlas Foundation offers programs such as a Think Tank MBA and Think Tank Leadership Training. Since 2001, *Prospect* magazine has organized an annual competition now described as 'the Oscars of the think tank world' by the BBC, to recognize important and influential work done by think tanks across the globe. There is a Facebook community – On Think Tanks! These initiatives and actors orbiting think tanks testify to the strength and tenacity of the think tank in contemporary policy processes and the political imagination.

In conclusion, the think tank, in all its diversity, has seen a century of growth in virtually all countries around the world. Moreover, these organizations have spread into international governance with developments like the *Think20* network seeking to inform and influence the G20. Yet, with rapid access to analysis and advocacy afforded by the internet, this century may witness less growth in the face of greater competition from NGOs, universities, and consultancy firms for policy influence and political attention.

Third World

Abstract

This article retraces definitions of the term *Third World* (*Tiers Monde*). The genesis, varied meanings, and popular uses of the concept show historical connections between globalizing capitalism and the emergence of colonial empires. The usefulness and limitations of Third World as an analytical, ideological, or political category are discussed. After World War II, the position of Third World nations changed again, and organizations such as the United Nations fostered enhanced status, sense of purpose, and solidarity among Third World nations. Understandings of what constitutes the Third World came about in the international system after the end of the Cold War. The article concludes with the relevance of the concept in the era of the United Nations Millennium Development Goals.

Defining the Third World

The *Third World* has become a convenient catch phrase that refers collectively to the large number of heterogeneous societies, cultures, civilizations, countries, territories, states, and nations of the non-Western world, most of which lie in the tropics, have experienced European conquest or colonial rule, whose economies are less industrialized or not completely modernized, whose political orders are often less democratic, more autocratic or authoritarian and prone to political instability including coups d'état and civil wars, and a majority of whose population has the lowest standards of living or are considered or consider themselves poor relative to those of the First and Second Worlds. The Third World includes all countries of Africa (except South Africa), Asia (except Japan), Latin America and the Caribbean, and most states and territories of Oceania (except Australia and New Zealand).

The Origin of the Term and Its Varied Meanings

The term *Third World* (*Le Tier Monde*) is of French origin. It was first used in France in the early 1950s by a number of French writers like Alfred Sauvy (politician, economist who is credited with coining the term in 1952) and Claude Boudel in the context of apparently increasing polarization of the international system into rival blocs. The term conveys a conscious echo of the older concept of *le tiers état* that is, *the third estate* (the common people, the poor and underprivileged) of the prerevolutionary *ancien régime*. Some claim that it was Frantz Fanon, a black French Caribbean writer and psychiatrist from Martinique (author of *The Wretched of the Earth*, 1963) who first used the term to refer to the poor decolonized and decolonizing societies and territories of Africa, Asia, Latin America, and the Caribbean. Educated in France, Fanon was a political activist who worked in Algeria, supported the Algerian nationalist struggle for independence from French occupation in the 1950s, and developed revolutionary theories for the decolonization of Africa. A weasel word, the term *Third World* has been used in several related senses, substituting for or succeeding other terms used by Europeans to refer to non-European peoples and cultures: *aboriginal*, *indigenous savage*, *barbarous*, *traditional*, (*primitive*, *tribal*, *peasant*) *native*, *Indian*, *Mohammedan*, *pagan*, *precapitalist*, *preindustrial*, *preliterate*, *non-Western*, *nonwhite*, *premodern*, and *black*. Such terms have been used sometimes with deliberate contempt and condescension, with pejorative connotations, or even racist overtones.

These terms have also been adopted by the educated, more privileged urban dwellers in the Third World itself.

Third World has also been employed as a shorthand euphemism for the social condition or plight of the very poor or powerless or underdeveloped society anywhere in the world, including the First and Second Worlds, even though a vast majority of the people fitting the description live in the Third World. In this sense, the phrase *America's Third World* refers to America's rural and urban poor: the black underclass, Native Americans, and rural whites in Appalachia. In a similar usage, the former Soviet Union was once described by the *Times* of London as having a Third World economy with First World weapons. South Africa is described as a First World society in which the Third World is ever present.

The term *Third World* has also been extended to the poorer Eastern European countries whose economies were subjected to the needs of and exploited by Northern Europe in the early modern period. In everyday use, the term has thus acquired loose, but frequently negative, social, cultural, political, economic, ideological, and racial meanings, often with a fine disregard for geography. From 1945 to 1989 a capitalist block (First World) led by the United States and a communist one (Second World) led by the Soviet Union fought a Cold War that ended with the collapse of the Soviet Union in 1991. In the Cold War context, the Third World consisted mostly of newly decolonized, uncommitted countries not aligned diplomatically with either the capitalist world or the communist world. But the two dominant historic models of development, capitalism and socialism, especially the former, continued to broadly shape the rate and direction of change in the Third World.

Third World as an Analytical Concept

Since World War II and the invention of the term, the conditions of Third World, and the relationship among the First (the

 http://dx.doi.org/10.1016/B978-0-08-097086-8.12154-3

rich Western industrialized capitalist countries), Second (the industrialized communist countries of the Soviet Union and Eastern Europe), and Third Worlds have been the focus of theory, intensive research, and extensive documentation aimed at explaining and understanding the nature, origin, and consequences of poverty and underdevelopment in the Third World, and of policy concerned with appropriate strategies for development and poverty alleviation. The leading theories of Third World development and underdevelopment include 'modernization theory,' 'dependency theory,' and 'world-system theory.' Some Marxist scholars have rejected the term *Third World* as a false concept masking the contradictions of capitalist development in the former European colonies (of conquest, exploitation, and settlement). Third World countries often see themselves as old or ancient societies 'lagging behind' economically, technologically, and even politically and thus trying to 'catch up' with (and even overtake) the more advanced industrialized countries of the First and Second Worlds.

The rise and spread of capitalism globally (1500s–1900s) was intimately linked to the growth of large, powerful oppressive and exploitative European colonial empires, inspired by the prevailing mercantilist philosophy of the early modern period dedicated to the unbridled pursuit of economic power and wealth of nation-states backed and secured by strong military presence.

Because of its vast natural resources and potential as sources of readily available cheap or unpaid labor (slave, indentured, semi-proletarian, etc.), which were largely untapped, its considerable potential commercial value and importance of some areas to white settlement and occupation, the Third World has been for over five centuries a principal focus of European territorial ambition and rivalry.

Most of the states and territories of the Third World took their present form in the nineteenth and early twentieth centuries when large parts of Asia and Africa were colonized by European imperial powers. By the 1880s the world had been carved up among a handful of European industrial powers. By 1914, European economic and political control covered most of the global land surface, claiming nearly the entire non-European world. Japan successfully resisted European colonization, and China was never formally colonized but for the highly lucrative treaty ports along the coasts, e.g., Hong Kong following the Opium Wars of the 1830s.

Latin America, conquered, colonized, and settled by the Portuguese and Spanish crowns three centuries before Asian and African colonization, was transformed into independent republics, along with formerly French Haiti in the Caribbean (the first black republic anywhere) in the early nineteenth century, after long, bloody, and bitter nationalist struggles.

Despite wide differences in local cultures, historical traditions, and responses to colonialism, colonies came to share several common features: political control from Europe; unchecked economic exploitation; Euro centrism; incipient Westernization; religious intolerance, especially against the so-called 'pagan' and other indigenous beliefs and practices (including Islam and Hinduism); and particularly in the black world, the construction and reproduction of a racist social order of which apartheid of South Africa was the most notorious recent example. Colonialism that followed the transatlantic slave trade in Africa, during which an estimated 10 million or more Africans were exported to provide unpaid labor for European plantations and mines of the Americas, did incalculable damage to black Africa, notwithstanding some lasting beneficial by-products: Christianity, schools, hospitals, and the start of modern administration. The colonial borders that were drawn across Africa divided African peoples and cultures, and along with the authoritarian and repressive colonial political tradition are largely responsible for much of the chronic poverty, cultural identity crisis, and political instability of independent African countries. One enduring legacy of European colonial empires is a global economic order with an asymmetrical North–South division between a rich industrial North of mostly former imperial powers and poor, less industrialized South of former colonies. The North–South divide is exacerbated by neocolonialist attempts to influence or exercise de facto control over the policies of the South through formal and informal alliances and agreements calculated to ensure the perpetuation of the hegemonic economic power of the North.

The United Nations and the Rise of the Third World

The United Nations (UN) charter endorsed the principle of self-determination and sovereign equality of all nations. After the late 1940s, the large ex-colonies like India, Pakistan, Egypt, and Indonesia, supported by Latin American countries, used the UN as a forum to press for an end to colonialism and rapid development of former colonies. The term *Third World* received formal endorsement following the Bandung conference of Asian and African states in Indonesia in April 1955, which affirmed the solidarity of the Third World and prepared for the birth of the nonaligned movement (NAM). At the conference, China declared herself a Third World country. As an expression of China's solidarity with the Third World, the Chinese leader Chou En Lai on a state visit to Conakry, Guinea, West Africa, spelled out the eight principles of Chinese aid to developing countries, to emphasize an obvious and sharp contrast between the Chinese approach to overseas aid and that of the dependence-creating objectives of Western economic, military, and technical assistance to developing countries of the Third World. The principles embodied China's commitment to making Chinese overseas aid mutually beneficial to both China and the recipient country with no political strings whatsoever attached. The term *Third World* was also adopted in the UN classification system to distinguish between the developed and underdeveloped or developing countries.

The conferences of NAM, the first one held in Belgrade (former Yugoslavia) in 1961 and the founding in June 1964 of the UN Group of 77, at the conclusion of the first UN conference on Trade and Development (UNCTAD), which was convened at the initiative of Third World countries, marked the growth of the Third World as a potent force in world affairs.

With approximately two-thirds of the total UN membership, the 1960s and 1970s witnessed the rapid rise in the power and sense of purpose of the Third World. The G-77 spearheaded the UN call for a New International Economic Order (NIEO) to reform the economic relations between the North and the South and to rectify the inequality evident in the

relative access of the rich and poor countries to markets, to supplies, to science and technology, and to credit, which implied a redistribution of wealth in favor of the South. The issue of North–South relations was made the subject of an international commission that met from 1977 to 1979 under the chairmanship of Willy Brandt.

By the 1990s, with the collapse of the Soviet Union and the end of bipolar politics, NAM and the G-77 which have a joint coordinating committee, shifted their focus to problems of underdevelopment, the Third World debt burden, trade liberalization, and aid.

The G-77, whose membership increased to 130 with the admission of postapartheid South Africa, believes that global shared prosperity through North–South cooperation on a fair and equitable basis is the only long-term remedy for Third World poverty and human misery.

Diversity, Division, and Integration

Depending on the definition and context, different countries or populations will make up the Third World. In 1989 before communism in the former Soviet Union and Eastern bloc countries (Second World) suddenly collapsed, the World Bank – the only global multinational development organization grouped countries by regions and by gross national product (GNP) per capita into three main categories as follows: (1) high income countries – 25 countries, 19 of which consisted mostly of the Western industrial developed countries, many of them former colonial powers, and Japan (First World). The remaining six countries – Hong Kong, Israel, Kuwait, Saudi Arabia, Singapore, and United Arab Emirates – had high GNP per capita but not necessarily at the same level of development as the Western industrial countries, with a total population of 0.8 billion; (2) developing countries (Third World) divided into (a) 42 low-income countries – with the lowest per capita income and a population of 2.8 billion; and (b) 53 middle-income countries, with per capita income slightly higher than that of (a) with a population of 1.1 billion. The total population of the 95 developing countries was 3.9 billion; and (3) nonreporting, nonmember countries – a mixed group of Second and Third World communist/socialist countries – e.g., USSR, Cuba, Albania, German Democratic Republic, Peoples Republic of Korea, Angola and Namibia, and countries (mostly islands) with populations of less than 1 million each. The total population of this group was 0.4 billion. The goal of economic development, for the World Bank, is to fight poverty and raise the living standards of low- and middle-income countries of the Third World. Clearly, more than three-quarters of all humanity live in developing countries of the Third World. By 2000, the Third World population was estimated to have risen to four-fifths of mankind. The developing countries as a whole, a very diverse group, accounted for more than two-thirds of the earth's land surface and 80% of the world's poor. Today (in 2012) of the estimated global population of 7 billion, only about 20% live in the rich, developed North – the overwhelming majority still living in the mostly impoverished but rapidly developing emergent market countries of the South, such as China, India, Brazil, Indonesia, Mexico, and South Africa. Accordingly, the Third World may be further divided into those states that have access to rich natural resources, faster growth rates, or better development potential, and those that do not. While the latter are sometimes described as the *Fourth World*, that term is probably more frequently used to refer to marginalized indigenous or tribal peoples. Despite internal divisions and differences, Third World countries share some common features as well as problems.

Most of the peoples of the Third World still suffer from hunger, disease, and lack of shelter, potable water, and opportunities (especially for women) to realize their potential as human beings. Third World countries are faced with crippling external debt burdens, poor social and physical infrastructure, and inadequate technology, making it difficult or impossible to recover from or respond effectively (without massive external help mostly from the First World) to natural disasters and civil conflicts to which many are prone. Because of the chronic and deepening poverty in the midst of burgeoning populations, diminishing natural resources, and increasingly degraded environments, these countries have also become major producers of massive illegal political and economic migrations to the more prosperous industrial capitalist North, and of economic and political refugees and internally displaced persons within the Third World itself.

The Third World and the Post-Cold War International System

The Third World as an ideological concept has been undermined by the end of the Cold War, the collapse of Soviet-style communism, and the increasing cooperation between the leading industrial capitalist nations – the G-7 and Russia. Its economic meaning has also been challenged by the fundamental changes in the world economy, brought about by the forces of globalization. The transition of the former Soviet Union and Eastern bloc countries and some Third World nations to pluralist democracy and market economies has made it increasingly difficult to distinguish between some First and Second World countries, and in some cases between Third World and Second World countries.

Given the wide range in the levels of economic development and standards of living within and between Third World countries, placing prosperous Hong Kong and impoverished Haiti, or industrializing Brazil and hunger-prone Bangladesh, in the same category is clearly questionable. Again, by the end of the twentieth century, new economic groupings made up of selected countries of the First, Second, and Third Worlds, some of them regional (e.g., NAFTA), were formed to promote regional prosperity; and others, cross-regional (e.g., Group of 20), emerged to foster dialogue if not unity of action between the rich industrial countries and countries of the emerging markets. The growing convergence of national and transnational economic and political interests has added a new challenge to the usefulness of the Third World as an economic or ideological category.

In the new strategic global environment, NAM also seems increasingly anachronistic. But the overall objectives of NAM, which include the pursuit of world peace, the elimination of disease, hunger, and ignorance; the conduct of international relations on the basis of respect for and understanding of other

cultures, systems, and values; and the elimination of all forms of neocolonialism and racism, make it still relevant.

The Third World, the Third Millennium, and the WORLD WAR ON WANT

In September 2000, at a special session of the UN General Assembly, 189 member states of the UN adopted an historic Millennium Declaration committing countries rich and poor to take concerted action to eradicate poverty, promote human dignity and equality, and achieve peace, democracy, and sustainable environment. The world leaders agreed on a set benchmark of eight Millennium Development Goals (MDGs) and related targets to guide developing countries to pursue programs along the agreed goals with the start date fixed at 1990 and the end date for achieving the goals of 2015 or earlier. The MDGs are as follows: eradicating extreme poverty and hunger; achieving universal primary education; promoting gender equality and empowering women; reducing child mortality; improving maternal health; combating HIV/AIDS, malaria, and other diseases; ensuring environmental sustainability; and developing a Global Partnership for Development. Indeed many developing countries were pursuing programs aimed at tackling the development challenges facing their countries and peoples. What the adoption of the MDGs did was to galvanize most leaders of the developing countries to undertake and aggressively pursue unprecedented measures aimed at meeting the needs of their most downtrodden, disadvantaged, and discriminated-against populations with the target dates in mind. Since 2001, the implementation of the MDGs has been transforming development and human lives in the Third World for the better. Governments, aid agencies, nongovernmental organizations (NGOs), and civil society organizations worldwide have been reorienting their development programs and work around the MDGs, including the construction of model Millennium Development villages to stimulate holistic and sustainable rural development.

The World Bank's Development Research Group in its estimates for global poverty updated from 2005 (its figures for people living in absolute poverty – that is both the number and proportion of the population living on less than the equivalent of $1.25 (US) a day (at 2005 prices) – the most commonly accepted poverty line) shows that in 2008, the first year of the global financial and food crises, absolute poverty was falling in every part of the world. This was the first instance of declines across the board since the World Bank started collecting the figures in 1981. The estimates for 2010, though incomplete, show global poverty that year was half its 1990 level. The world thus reached the UN's MDG of halving world poverty between 1990 and 2015, 5 years early.

Significantly, much of the credit for this unusual reduction in poverty goes to the emerging powers/markets, especially the so-called BRICS countries – Brazil, India, Russia, China, South Africa – and led by China. Fifty percent of the long-term rate of world poverty decline is attributable to China alone, which has pulled more than half a billion (660 million) people out of poverty since 1981. Of the roughly 1.3 billion people worldwide, living on (the equivalent of) less than $1.25 (US) a day in 2008, 1.1 billion of them were outside China. China also accounts for most of the rapid progress in East Asia, which in the early 1980s had the highest poverty rate in the world with 77% of the population living below the poverty line.

Africa has also seen the largest recent long-term improvement in poverty reduction. The number of people in poverty in sub-Saharan Africa almost doubled from 205 million in 1981 to 395 million in 2005. But in 2008 it fell by 12 million to 47%, the first time less than half of the African population has been below the poverty line. The number of poor people in Latin America had also been rising (from lower levels) as in Eastern Europe and Central Asia. But these regions have reversed the trend since 2000.

The positive turn in economic and social progress in many Third World countries reflects the long-run high rates of sustainable growth in China, which has replaced Japan as the world's second largest economy after the United States. China trade and investment abroad is reshaping the twenty-first century world. Equally important in poverty reduction in Africa and Latin America are good governance; political stability; the global spread of access to credit through microfinance, especially by women; the rising prices for Third World principal export commodities; and the social programs pushed by democratically elected populist or leftist governments in Brazil, Venezuela, and Bolivia that have greatly boosted social spending to help the poorest of the poor in urban slums and rural farms making less than $1.25 (US) a day.

Among the developing countries that have either halved poverty already or are expected to do so by 2015 are Cambodia and Ghana. Overall, 88% of developing countries should meet the Millennium Development poverty goal. Indeed, the world is on track to halve extreme hunger in many of the same countries where poverty is declining. About 45% of Third World nations have already reached this goal, and another 33% are close to reaching it. Again 83% of developing countries are either close to reaching the goal of providing universal primary education or have reached it. Achievements of MDGs have been helped by the big rise in inter–Third World aid and by improvements in systems of technical assistance and aid delivery, including e-health diagnosing by direct teleconferencing. Between 2005 and 2010 Brazil, which has replaced the United Kingdom as the world's sixth largest economy, and India grew their foreign aid spending by more than 20%. This type of aid using low-cost resources and strategies has proven more efficient and effective in reaching large populations in nonurban settings in the global South.

The number of people living below the poverty line worldwide is projected to be 883 million in 2015 compared with 1.4 billion in 2005 and 1.8 billion in 1990. But within developing countries that are making progress toward MDGs, there still exist persistent pockets of deprivation with concentrations in urban slums among society's excluded populations and in the countryside. In most of the Third World there is a disturbing contrast between a growing, yet still relatively small middle-class elite and the large majority of people left behind. There is also a lower tier of countries, mostly in sub-Saharan Africa, that remains trapped in extreme poverty and misery. Many of these are either landlocked states or states with few natural resources, degraded

environments, or ineffective or corrupt and/or unstable governments.

Taking a long-range view of the Third World the experts estimate, based on the developing world's high growth rates from the middle of the last decade and its enormous development potential, that by 2050, 80% of future global growth will be from the emerging markets in Asia, Africa, and South America, and the future prosperity of the developed West will be linked to the success of those countries led by China, India, Brazil, Indonesia, South Africa, and the rise of the rest. The major players in the developing world are already catching up to or even surpassing their counterparts in the developed world. The convergence of the economies of the Third World (with Russia in solidarity with the Third World) and those of the First World would seem to be the order of the day. This could usher in a new world order, not dominated by any one superpower, but a world more united, more peaceful, more just, and more equal, that is a truly one-world order.

Abstract

'Whatever exists at all exists in some amount. To know it thoroughly involves knowing its quantity as well as its quality' (Thorndike, 1918, p. 16). Few careers as diverse as that of Edward Lee Thorndike could be summarized so succinctly. Yet the hallmark of all the work of this extremely prolific psychologist was his abiding faith in the quantifiability of all aspects of human experience. From his first abortive attempts in 1896 to study mind reading through his last publication on shifts of interest with age, he was committed to quantification and, where possible, the controlled experiment. He applied empirical methods to topics as diverse as animal experimental psychology, the scientific study of education, and lexicography. 'Professor Thorndike's major life-purpose was … to demonstrate the unrivalled fruitfulness of the scientific method in the solution of social problems and to introduce it in exacting, quantitative forms which had been so productive in the physical fields' (Gates, 1949, p. 31).

'Whatever exists at all exists in some amount. To know it thoroughly involves knowing its quantity as well as its quality' (Thorndike, 1918, p. 16). Few careers as diverse as that of Edward Lee Thorndike could be summarized so succinctly. Yet the hallmark of all the work of this extremely prolific psychologist was his abiding faith in the quantifiability of all aspects of human experience. From his first abortive attempts in 1896 to study mind reading through his last publication on shifts of interest with age, he was committed to quantification and, where possible, the controlled experiment. 'Professor Thorndike's major life-purpose was to demonstrate the unrivaled fruitfulness of the scientific method in the solution of social problems and to introduce it in exacting, quantitative forms which had been so productive in the physical fields' (Gates, 1949, p. 31).

Life Events

E. L. Thorndike was born August 31, 1874 in Williamsburg, Massachusetts, the second son of Edward Roberts and Abbie (Ladd) Thorndike. The senior Thorndike was a Methodist minister who served churches in Maine and Massachusetts. The family often spent parts of their summers during E. L. Thorndike's childhood at an evangelical Methodist camp meeting on Martha's Vineyard. Perhaps in part as a reaction to the intensely religious nature of his upbringing, E. L. Thorndike rejected religious practices almost as soon as he left home for study at Wesleyan University. Throughout his life, he maintained a posture that favored science over religion.

After graduating with highest honors from Wesleyan in 1895, Thorndike went to Harvard University to study with William James (see *James, William* (*1842–1910*)). It was under James that he began his psychological studies, first of mind reading (a failure), then of learning (a success). The course of his studies for the next two years took him from William James at Harvard to James McKeen Cattell at Columbia, and from maze learning in chicks to his famous puzzle box studies with cats, in which he traced for the first time the trial-and-error learning process as his hungry subjects attempted to escape from crude cages to reach food. His doctoral dissertation describing these experiments, *Animal Intelligence: An Experimental Study of the Associative Processes in Animals* (1898), is one of the most well-known and influential studies in all of psychology.

Upon completion of his doctorate, Thorndike took a position at Western Reserve University. After one year he gladly accepted an invitation to return to New York City and become a member of the founding faculty at Teachers College in the fall of 1899. Thorndike remained at Teachers College until his retirement in 1940, a period that saw the publication of approximately 450 books, monographs, and papers. Another 70 were published in retirement.

Thorndike married Elizabeth Moulton on August 29, 1900. They had four children who survived infancy. Feeling his own training had been very deficient in mathematics, Thorndike insisted that all his children develop a solid background in mathematics. All of the children earned doctorates in scientific fields, and the second son, Robert L., followed in his father's footsteps so closely that he eventually occupied E. L.'s office at Teachers College.

E. L. Thorndike's work was widely recognized within his own lifetime. He was elected President of the American Psychological Association in 1912, President of the American Association for the Advancement of Science in 1933, and served as Second President of the Psychometric Society in 1936. In 1925 he was awarded the Butler medal in gold by Columbia University. Cattell found him ranked first among American psychologists in a 1921 poll for American Men of Science. Many of Thorndike's friends and colleagues said he was a 'workaholic,' but what he enjoyed more than anything was simply messing around with data. Other than tennis (he built his own court) and golf (he used a putter anywhere within 50 yards of the green), his recreation was analyzing data. Retirement was not a happy time for Thorndike. His health was not good: he had been a heavy smoker and quite overweight much of his adult life, and he suffered from arteriosclerosis. But what troubled him most in his old age was an acute awareness of his own declining cognitive abilities. His mind was no longer capable of the feats of reasoning that had been central to his professional life (R. L. Thorndike, personal communication). He died of a massive cerebral hemorrhage, at his home in Montrose,

New York, on August 9, 1949, the day on which plans to celebrate his 75th birthday were to be finalized.

Thorndike's Research and Theory

As a result of his experiments with learning in cats, E. L. Thorndike formulated a theory of mental associations which he called connectionism. He believed that the central nervous system was the basis of all behavior, that learning and other behavioral modifications took place when connections were formed between neurons, and that there was a continuity among species and a similar continuity in human development. 'The intellectual evolution of the race consists in the number, delicacy, complexity, permanence, and speed of formation of associations. In man this increase reaches such a point that an apparently new type of mind results, which conceals the continuity of the process' (Thorndike, 1901, p. 65).

It has been suggested that Thorndike was driven to applied work with humans by employment pressures. This may have been true for Robert Yerkes (Thorndike, 1990) but in E. L. Thorndike's case his first interest was humans and he resorted to animal research 'because they wouldn't let him work with children' (R. L. Thorndike, personal communication).

Upon returning to Columbia, Thorndike quickly turned his attention to human problems. He was fascinated by individual differences, trying to measure them, explain them, and use them for prediction. He believed, as did many of his generation, that science could solve all human problems, and he set out to apply scientific method to problems of education. Much of the remainder of his career was spent trying to develop methods to measure individual differences and to use these measurements to make education more efficient and successful.

Thorndike set out immediately to place education on a sound scientific footing. Educational practice of the time, the doctrine of mental discipline, was guided by 'the teachers' faith that mental abilities are so little specialized that improvement in any one of them will help all the rest; manual training is often introduced into schools on the strength of somebody's confidence that skill in movement is intimately connected with efficiency in thinking' (Thorndike, 1903, p. 2).

Curriculum was founded on opinion, not evidence. Based on his transfer of training studies with Woodworth (Thorndike and Woodworth, 1901) and similar studies he and his students conducted, he concluded that 'since those who succeed in the study of Latin are better at general discrimination and judgment than those who fail, we conclude that learning Latin vastly improves general discrimination and judgment ... It suits the vanity of educational theory to fancy that the changes [that result from study] are wholly due to discipline' (Thorndike, 1903, p. 93).

Thorndike continued his pursuit of quantification and applying scientific method in education with his publication of one of the first books on psychological and educational measurement and statistics in 1904. Here he noted the difficulty of defining interval scales for measuring cognitive activities, advocated the use of norm-referenced measurement as pioneered by Galton, and sounded a strong warning concerning the reliability and validity of measurements.

From the beginning, Thorndike adopted the view that inherited differences in cognitive abilities were important. 'There is no reason to suppose that the brain is less influenced by [immediate ancestry] than the tissues that cause height. ... Immediate ancestry is thus the probable cause for original mental nature' (Thorndike, 1903, p. 53). 'The schools always have and always will work to create a caste, to emphasize inequalities. Our care should be that they emphasize inequalities, not of adventitious circumstances, but of intellect, energy, idealism, and achievement' (p. 96). Thorndike was a thoroughgoing intellectual meritocrat, but he opposed discrimination on any other basis.

The rise of behaviorism in the 1920s shifted psychological research away from an interest in 'original nature' for almost 60 years. Many of the findings of modern behavioral genetics and cognitive psychology support positions Thorndike proposed at about the time genes were being rediscovered or the mind was being banished from psychology. For example, he argued that there was an interaction between genotype and environment. Anticipating current thought, he suggested that 'Each nature in some measure selects its own environment, and each nature may get from an environment a different influence' (Thorndike, 1911, p. 48).

In addition to his efforts to make education more efficient and scientifically sound, Thorndike expended considerable effort from 1900 to 1925 in developing measures of what he referred to as intellect. He rejected the notion proposed by Charles Spearman that there was a single mental trait of intelligence, arguing instead that each test must specify what aspects of intellect it was designed to measure (see Thorndike, 1990 for a description of the Spearman–Thorndike debate). Beginning in 1903, and anticipating more popular work by Alfred Binet (see Binet, Alfred (1857–1911)), Thorndike and his students developed a wide variety of measures of human abilities. The work culminated in the CAVD, a 'test constructed (from 1922 to 1925) as a sample of what a measuring instrument for a mental ability should be' (Thorndike, 1949, p. v). With the CAVD, Thorndike (Thorndike et al., 1927) produced a test that would foreshadow item response theory and the test design methods of the 1990s.

In the 1930s, Thorndike turned his attention to issues of social science and social value. He pioneered the scientific study of environmental quality with his research on urban environments in Your City (1939) and he subjected the domain of values to scientific scrutiny in *Science and Values* (1936). But perhaps Thorndike had his greatest impact during this period through his contributions to lexicography. In the 1930s Thorndike revolutionized the dictionary by placing the design of these reference works on an empirical footing.

For years Thorndike had been collecting data on the relative frequency of words in published English. A list of the most frequently appearing 20,000 words, along with their relative frequencies, was published in 1931. The list was expanded to 30,000 entries in 1944. Thorndike used word counts to determine which words should appear in his dictionary, and semantic counts (the most common meanings of each word) were used to select the definitions and their order. In addition, Thorndike insisted that each word be defined only in terms of words that would be more familiar than the one being defined. The Thorndike Century Junior Dictionary, published in 1935,

was the first dictionary to use these principles and to focus its content on the needs of its most probable users. By 1950, the three Thorndike Century dictionaries dominated the field of dictionaries in education, and every serious competitor was copying his approach. All modern dictionaries follow his pattern.

E. L. Thorndike's influence is so pervasive in modern education and psychology that it is almost impossible to detect. If his contributions to lexicography were not enough, he pioneered the scientific study of education, made major contributions to psychological and educational measurement and testing, and put comparative psychology on a firm experimental footing. There is hardly a specialty in either field, with the possible exception of some clinical areas, that has not been significantly touched by his work or that of his hundreds of students, a list of which would read like a Who's Who of psychology and education in the middle and latter half of the twentieth century, including Abraham Maslow (who rejected his empiricism) and Raymond Cattell (see Cattell, Raymond Bernard (1905–98)) (who embraced it). A fairly complete list of the publications of E. L. Thorndike is available in Gates (1949); a full biography is given in Joncich (1968).

Abstract

This article focuses on signal detection and information-processing models for time perception. The pseudologistic model and the scalar timing model are presented as exemplars of these two classes of models. For both models Weber's law describes the relationship between variability in perceived time and mean perceived time, and a power function with an exponent close to 1.0 describes the relationship between mean perceived time and clock time. The application of the two models to the temporal bisection task is considered.

Time perception is a distinct area of study with its own psychophysical methods designed for assessing the perceived duration of a temporal interval. There is now an extensive database to guide the development of models of time perception. Most timing models are firmly rooted in an *internal clock*. Internal clock models postulate a timing-specific mechanism which produces perceived temporal values that bear orderly relations to real time. This timing-specific mechanism, or internal clock, is an interval timer, rather than a periodic or oscillatory mechanism. A periodic clock, such as the kind responsible for circadian rhythms, is continuously running and self-sustaining. In contrast, interval clocks need to be initiated with a signal. Once started, the system goes to completion, comes to a rest on its own, and must be restarted.

The first psychophysical models for time perception were proposed at about the same time by Creelman (1962) and Treisman (1963). Creelman (1962) introduced the signal-detection approach, which was continued by Allan and Kristofferson (1974). The most sophisticated signal detection model is Killeen et al.'s (1997) *Pseudo-logistic model* (PLM). The information processing approach was introduced by Treisman (1963) and continued by many others, including Eisler (1975), Thomas and Cantor (1978), and Zakay and Block (1994). The most developed of the information-processing models is Gibbon et al.'s (1984) *Scalar timing* (ST), which has been reformulated as a connectionist model by Church and Broadbent (1991). In direct contrast to information-processing models is Killeen and Fetterman's (1988) behavioral theory of timing (BeT).

Because signal-detection models and information-processing models have been applied to both human and nonhuman timing data, we shall focus on such models in this article, presenting ST and PLM as exemplars of these two classes of models. Specific versions of ST and PLM have been derived for a variety of timing tasks, such as time-left, temporal generalization, and *temporal bisection*. We shall examine ST and PLM in their application to temporal bisection.

In the prototypic temporal bisection task (e.g., Allan and Gibbon, 1991), the subject is familiarized with a constant pair of referents, one short (S) and the other long (L). On probe trials, a temporal interval t, $S \leq t \leq L$, is presented, and the subject is required to indicate whether t is more similar to $S(R_S)$ or to $L(R_l)$. Temporal bisection data are summarized as a psychometric function relating the proportion of long responses, $P(R_L)$, to probe duration t. The *bisection point* ($T_{1/2}$) is the value of t at which R_S and R_L occur with equal frequency, $P(R_L) = 0.5$. One interpretation of $T_{1/2}$ is that it is the point of subjective equality (PSE), identifying the perceived value of t that is midway between S and L. Empirically, it has been found that the location of $T_{1/2}$ is influenced by the size of the L-to-S ratio (r) and by the spacing of the probes (see Allan, 1998). For $r \leq 2$, $T_{1/2}$ is around the geometric mean (GM) of the S and L referents, but moves toward their arithmetic mean (AM) as r increases. For $r > 2$, $T_{1/2}$ for linearly spaced probes is greater than that for logarithmically spaced probes, with the probe spacing effect becoming negligible for $r \leq 2$.

Scalar Property

Both ST and PLM incorporate *Weber's law* for the duration values used in most psychophysical experiments. According to Weber's law, for a given clock time $t > 0$, the variability in perceived time (σ_t) is *scalar* with mean perceived time (μ_t); that is, there is a constant $\gamma > 0$ such that

$$\frac{\sigma_t}{\mu_t} = \gamma \qquad [1]$$

Also, for both models, mean perceived time is a power function of clock time with an exponent close to 1.0, i.e.,

$$\mu_t = t \qquad [2]$$

and therefore eqn [1] can be rewritten as

$$\frac{\sigma_t}{t} = \gamma \qquad [3]$$

The scalar property in eqn [3] results in distributions that superpose when the temporal axis is normalized with respect to the mean of the distribution. This superposition in relative time reflects a rescaling in time, a scale-invariant error distribution for perceived time.

Scalar Timing

ST has its origins in scalar expectancy theory (Gibbon, 1977), and made its appearance as a timing model in Gibbon et al. (1984). The model consists of three, interrelated information

processing stages – clock, memory, and decision – which are associated with timing, storage, and responding, respectively. The clock is responsible for transforming clock time into perceived time. It consists of a pacemaker that emits pulses at some mean rate, a switch that is controlled by a timing signal, and an accumulator that sums the pulses. There are two memory registers for the storage of clock information, *working memory* and *reference memory*. Working memory is loaded from the accumulator and serves as an extended buffer for temporal information from the current trial. Reference memory stores critical temporal information from past trials. The comparator determines a response on the basis of a decision rule which involves a comparison of current time stored in working memory with remembered time sampled from reference memory.

According to ST, the decision to respond R_S or R_L in temporal bisection is made by comparing the similarity of the perceived value of t with memories of the two referents, S and L. This comparison is based on a ratio of the similarity of t to S relative to the similarity of t to L. If that ratio is less than some fixed value β, the response is R_L. In his mathematical derivation of the *bisection function*, Gibbon (1981) combined the similarity ratio decision rule with two locations for the scalar variability, perception or memory. In the referent known exactly (RKE) model, he assumed no variability in the memory for the referents and placed the scalar variability in the perception of the probes. In contrast, in the stimulus known exactly (SKE) model, he assumed no variability in the perception of the probes and placed the scalar variability in the memory for the referents. There are two parameters in these models. The noise parameter γ is the coefficient of variation of time. For SKE, γ is the scalar variability in the memory representations of the S and L referents; for RKE, γ is the scalar variability in the perception of t. For both models, β is a response bias parameter. It follows from the assumptions of the model that the SKE bisection function is approximately

$$P(R_L) = 1 - \phi\left[\frac{1 - \beta\left[\frac{t}{\sqrt{SL}}\right]^2}{\gamma\sqrt{\gamma^2 + 2}}\right] \quad [4]$$

and the RKE function is approximately

$$P(R_L) = 1 - \phi\left[\sqrt{\frac{SL}{\beta\gamma^2 t^2}} - \frac{1}{\gamma}\right] \quad [5]$$

where ϕ is the cumulative normal distribution function. For both models, $T_{1/2}$ is proportional to the geometric mean (GM) of the S and L referents:

$$T_{1/2} = \sqrt{\frac{SL}{\beta}} = \frac{GM}{\sqrt{\beta}} \quad [6a]$$

and for unbiased responding ($\beta = 1$), $T_{1/2}$ is at the GM of the S and L referents:

$$T_{1/2} = \sqrt{SL} = GM \quad [6b]$$

Equation [6a] provides for variables such as ratio and probe spacing to have their effect on the location of $T_{1/2}$ through β. For example, with a large r and linear probe spacing, $T_{1/2}$ located at the GM would yield more R_L than R_S responses. To balance the frequency of the two response categories, it would be necessary to set $\beta < 1$, moving $T_{1/2}$ towards the AM. With log probe spacing, however, the two response categories would be equal with $\beta = 1$ and $T_{1/2}$ at the GM.

Pseudologistic Model

In addition to deriving the bisection function for the similarity ratio rule, Gibbon (1981) also derived the function for the signal detection likelihood ratio rule. For the likelihood rule, the decision to respond R_S or R_L is based on the odds ratio that the perceived value of t is generated by S or L. For this rule, Gibbon (1981) placed the scalar variability in the perception of the probes, resulting in a signal-detection model for temporal bisection. Killeen et al. (1997) simplified the derivation of the bisection function (and the resulting equation) by approximating the normal distribution with the logistic. The pseudologistic bisection function is

$$P(R_L) = \left[1 + \exp\left[\frac{C - t}{0.55\gamma t}\right]\right]^{-1} \quad [7]$$

where C is the signal detection criterion. According to PLM, $T_{1/2}$ is the value of t where the S distribution crosses the L distribution. Killeen et al. (1997) showed that $T_{1/2}$ is proportional to the harmonic mean (HM) of S and L; i.e.,

$$T_{1/2} = (1 + k)\frac{2}{\frac{1}{S} + \frac{1}{L}} = (1 + k)HM \quad [8]$$

where

$$k = \left[\frac{\gamma \ln\left[\frac{L}{S}\right]}{2}\right] \quad [9]$$

PLM predicts that the L-to-S ratio will affect the location of $T_{1/2}$.

PLM is presented schematically in **Figure 1** for $r = 4$ ($L = 8$ and $S = 2$). The spacing of t is linear, $\gamma = 0.15$, and C is located at $(1 + k)HM$. It is clear from **Figure 1** that because of the scalar property a percept located at $C = (1 + k)HM$ is more likely to have been generated by L than by S. Killeen et al. (1997) suggested that in order to balance the frequency of the two response categories, C would move toward the AM with increasing r rather than being set at $(1 + k)HM$.

Pseudologistic Model and the BeT

Killeen et al. (1997) emphasized that PLM is a descriptive rather than a process model in that it resides close to the level of the data and does not postulate particular underlying processes that generate the data. They do describe, however, how in their view PLM dovetails with BeT.

Other Models

Allan and Kristofferson (1974: 26) concluded that "There are few quantitative theories of duration discrimination and few

Figure 1 Schematic of the PLM model for $r = 4$ ($L = 8$ and $S = 2$). The logistic density functions [f (t)] are for $t = 2$, 4, 6, and 8. The psychometric function [$P(R_L)$] is for C located at $T_{1/2} = (1 + k)HM$ and $\gamma = 0.15$.

established empirical phenomena to guide theorizing." Five years later, Allan (1979: 340), referring back to Allan and Kristofferson (1974), stated that "Since that time, there has been a dramatic change. Many articles on the discrimination of brief temporal intervals, and several new quantitative models, have appeared in a period of a few years." Now in 2000 we have an abundance of quantitative models for time perception. In this short article, I have merely provided the reader with a few gems. To obtain a broader exposure to and appreciation of the current status of quantitative models for time perception, the reader is referred to two special issues of *Behavioural Processes* in 1998 and 1999 edited by Jennifer Higa.

Abstract

Recent developments in the time-domain analysis of time series are reviewed. The concept of dynamical systems serves as a unifying theme of the review. We consider first methods for the modelling of the drift component or the conditional mean of a time series. This includes the class of threshold models and its variants. We then consider methods for the modelling of the diffusion component or the conditional variance of a time series which includes the popular generalized autoregressive conditional heteroscedastic G(ARCH) models and the stochastic volatility (SV) models. Hybrid models for the modelling of both the drift and the diffusion are then introduced. Long memory and discrete-valued time series models are also included. The main focus is on univariate series although multivariate series are also mentioned where appropriate.

Introduction

Many social phenomena can be described, at least approximately, by a discrete-time dynamical system, which can be expressed as a difference equation,

$$Y_t = F(X_{t-1}) \qquad [1]$$

where $\{Y_t\}$ is a sequence of m dimensional observations and X_t is a d' dimensional state vector, with $t = 1, 2, \ldots$ and $1 \le m' \le m$. In many applications, X_t stands for the past values of Y_t. Depending on the functional form $F(\cdot)$, the difference eqn [1] can exhibit a variety of dynamical features such as limit cycles, time irreversibility, and periodic changes (Tong, 1983, 1990). However, in the real world, stochastic noise is often present and therefore it is more realistic to consider a dynamical system with noise such as:

$$Y_t = F(X_{t-1}, a_t; \theta) \qquad [2]$$

where $\{a_t\}$ is often assumed to be a sequence of independent identically distributed (*i.i.d*) (possibly vector valued) random variables and θ is a vector of parameters. For instance, if $Y_t = X_t$ with $m = 1$ and $F(\cdot)$ is a scalar valued function, say, $f(X_{t-1}; \theta) + a_t$, then (2) takes the form:

$$X_t = f(X_{t-1}; \theta) + a_t \qquad [3]$$

which is a nonlinear autoregressive process of order one. Clearly eqn [3] can be generalized to include more past values of X_t and then we have

$$X_t = f\left(X_{t-1}, X_{t-2}, \ldots, X_{t-p}; \theta\right) + a_t \qquad [4]$$

which is a general nonlinear autoregressive process of order p. An important special case of eqn [4] is when $f(\cdot)$ is linear in the past values of X_t and we have then

$$X_t = \phi_1 X_{t-1} + \ldots + \phi_p X_{t-p} + a_t \qquad [5]$$

which is the usual linear autoregressive model of order p. Depending on $f(\cdot)$ or more generally $F(\cdot)$, the number of nonlinear models is clearly unlimited and the choice of a model is typically dictated by the situation and the ability of the model to describe/predict a social phenomenon.

It is clear that the dynamical system formulations eqn [2] and eqn [4] can be extended by considering a specification of the variance of the noise term a_t. Thus,

$$X_t = f(X_{t-1}; \theta) + g(X_{t-1}; \theta) a_t \qquad [6]$$

where $g(\cdot)$ is positive. Now, X_t is conditionally heteroscedastic. In other words, model eqn [6] now consists of both specifications for the mean (the drift) and for the conditional variance (the diffusion). Below we consider some advanced models in time series which have been developed and found to be useful since around 1980. For simplicity, we let $Y_t = X_t$ and a_t be a sequence of *i.i.d.* scalar random variables.

Nonlinear Time Series for the Mean

The Class of Threshold Models

Proposed by Tong in the later 1970s, the threshold models are a natural generalization of the linear autoregression eqn [5] by allowing different linear autoregressive specification over different parts of the state space. For example, a two-regime threshold autoregressive model of order p_1 and p_2 may be defined as follows:

$$X_t = \begin{cases} \phi_0^{(1)} + \phi_1^{(1)} X_{t-1} + \ldots + \phi_{p_1}^{(1)} X_{t-p_1} + a_t^{(1)}, & \text{if } X_{t-d} \le c \\ \phi_0^{(2)} + \phi_1^{(2)} X_{t-1} + \ldots + \phi_{p_2}^{(1)} X_{t-p_2} + a_t^{(2)}, & \text{otherwise} \end{cases} \qquad [7]$$

where $1 \le d \le \max(p_1, p_2)$, $\{a_t^{(i)}\}$ are two *i.i.d.* noise sequences with mean zero and variance σ_i^2, $i = 1, 2$, $\{a_t^{(1)}\}$ and $\{a_t^{(2)}\}$ are also independent of each other. We call c the threshold parameter and d the delay parameter. Equation [7] is called a self-exciting threshold autoregressive (SETAR $(2; p_1, p_2)$) model. Generalizations to more than two regimes are immediate. Stationarity and ergodicity conditions for eqn [7] when $p_1 = p_2 = 1$ and $\phi_0^{(i)} = 0$, $i = 1, 2$ have been obtained while a sufficient condition for the general SETAR $(2; p, p)$ model is available (Tong, 1990).

Estimation of eqn [7] can be easily done using the conditional least squares method given the parameters p_1, p_2, c, and d. Identification of p_1, p_2, c, and d can be done by the minimum Akaike information criterion (AIC) (Tong, 1990). For finite samples the corrected AIC or AICC is recommended (Wong and Li, 1998). The computer programme STAR 3 accompanying Tong (1990) provides a comprehensive set of modeling tools for threshold models. Diagnostic checking for model adequacy can be done using residual autocorrelations. The appropriate asymptotic distribution was derived in Li (1992). Tsay (1989) suggested an approach in the detection and modeling of threshold structures which is based on explicitly rearranging the least squares estimating equations using the order statistics of X_t, $t = 1,\ldots, n$, where n is the length of realization. (see Tong, 1990 for references.) A similar rearrangement was incorporated in the software STAR 3. Chen and Tsay (1993) considered a functional-coefficient autoregression model which has a very general threshold structure.

An easy-to-use statistic for detecting departure from linearity is the port-manteau test based on squared residual autocorrelations, the residuals being obtained from an appropriate linear autoregressive moving-average model fitted to the data (McLeod and Li, 1983). Of course, a general test statistic may not be optimal in terms of power when specific alternative hypotheses are considered. Tong (1990) has described other tests for nonlinearity due to Davies and Petruccelli, Keenan, Tsay and Saikkonen and Luukkonen, Chan and Tong. Petruccelli (1990) considered a comparison for some of these tests.

As a textbook-like example (albeit outside the social sciences), we consider the annual Canadian lynx trapping data in the MacKenzie River for the period 1821–1934. The nonlinearity of the data has been extensively documented by Tong (1990). Threshold nonlinearity was confirmed by applying the likelihood ratio test of Chan and Tong (1986) at the 1% percent level. Following other authors we transform the data by taking common log. We use the AICC as a criterion in selecting the best SETAR (2; p_1, p_2) model. The maximum possible value for p_1 and p_2 is 10, and the maximum possible value for the delay parameter d is 6. It is recommended that possible candidates of the threshold parameter can be chosen from a subset of the order statistics of the data. Following Wong (1998) we use 2.4378, 2.6074, 2.7769, 2.9464, 3.1160, 3.2855, and 3.4550, as potential values of the threshold parameter. The best fitting model using the minimum AICC criterion is the following SETAR (2; 4, 2) model,

$$\begin{aligned} X_t &= 1.0303 + 0.8959X_{t-1} - 0.0313X_{t-2} + 0.0406X_{t-3} \\ &\quad - 0.2001X_{t-4} + a_t^{(1)} \\ &\quad \text{if } X_{t-3} \le 2.9464, \\ X_t &= 1.6092 + 1.3487X_{t-1} - 0.8937X_{t-2} + a_t^{(2)}, \\ &\quad \text{if } X_{t-3} > 2.9464 \end{aligned}$$

where $a_t^{(1)}$ and $a_t^{(2)}$ have estimated variance equal to 0.0164 and 0.0642, respectively. The residual autocorrelation and squared residual autocorrelation show no significant values suggesting that the above model is adequate.

Instead of adrupt jumps between regimes in eqn [7] a smooth transition threshold autoregression was proposed by Chan and Tong (1986). Teräsvirta (1994) considered some further work in this direction. Continuous time threshold model was considered by Tong and Yeung (1991) with applications to water pollution data. Brockwell (1994) and others considered further work in the continuous time. Multivariate (mainly bivariate) threshold models were included in the seminal work of Tong in the 1980s and further developed by Tsay (1998). The relation between chaos and nonlinear time series is also treated in some detail in Tong (1990).

The Class of Bilinear Time Series Models

Bilinear models featured for a while in the early days of nonlinear time series modeling. In its simplest form, a single term bilinear model is given by

$$X_t = \beta X_{t-k} a_{t-l} + a_t \qquad [8]$$

where k, $l \ge 1$. Note that eqn [8] is linear in $X_{t-k}(a_{t-l})$ given $a_{t-l}(X_{t-k})$.

Granger and Andersen (1978) provided the first comprehensive introduction to these models. By deriving the second order autocovariances of eqn [8], they demonstrated that if $l < k$ then the time series cannot be distinguished from an uncorrelated noise process. The general bilinear autoregressive moving average model of order (p, q, P, Q) has the form

$$X_t = \sum_{j=1}^{p} \alpha_j X_{t-j} + \sum_{i=0}^{q} b_i a_{t-1} + \sum_{k=1}^{P} \sum_{l=1}^{Q} \beta_{kl} X_{t-k} a_{t-l} \qquad [9]$$

Granger and Andersen (1978: 31) denoted this by BARM (p, q, P, Q) and Subba Rao (1981) denoted this by $BL(p, q, P, Q)$. Subba Rao (1981) and Subba Rao and Gabr (1984) gave a general theory for model (9). Further results on causality and stationarity were given by Liu and Brockwell (1988). Identification (in the sense of estimation) of model (9) is in general difficult because of the enormous number of possibilities.

Models with Conditional Heteroscedasticity

One very popular class of such models is the autoregressive conditional heteroscedastic (ARCH) models of Engle (1982). The ARCH model of order one (ARCH(1)) is given by

$$X_t = \sqrt{h_t} a_t \qquad [10]$$

and $\sqrt{h_t} = g(X_{t-1}; \theta) = (\alpha_0 + \alpha_1 \alpha_{t-1}^2)^{\frac{1}{2}}$. Here $\alpha_0 > 0$, $\alpha_1 \ge 0$ and a_t is again *i.i.d.* with mean zero and unit variance. It can be shown that X_t is covariance stationary if $0 \le \alpha_1 < 1$. The unconditional variance of (6) is then $\alpha_0/(1-\alpha_1)$. The fourth moment of (6) exists if $\alpha_1^2 < \frac{1}{3}$. It is then greater than 3. For $r > 1$, the ARCH(r) model is defined by including more past values of X_t^2 so that X_t^2 X_t^2 X_t^2 $h_t \equiv E_t^2 \mid$ *past information* $= \alpha_0 + \alpha_1 X_{t-1}^2 + \cdots + \alpha$, X_{t-r}^2 ($x_0 > 0$, $\alpha_i \ge 0$ X_t^2 X_t^2 X_t^2 X_t^2). Again, X_t is covariance stationary if $\alpha_1 + \alpha_2 + \cdots + \alpha_r < 1$. It can be shown that the autocorrelation function of X_t^2 behaves like that of an AR(r) process. Milhøj (1985) derived the condition for the existence of the $2m$-th moments of X_t. Estimation of model 10 can easily be done by assuming a_t to be

standard normal so that X_t is conditionally normal with mean zero and variance h_t. The conditional log likelihood l is then given by

$$l = \sum_{t=1}^{n} l_t = \sum_{t=1}^{n} -\frac{1}{2}\log h_t - \frac{1}{2}\frac{X_t^2}{h_t}. \qquad [11]$$

Maximum likelihood (ML) estimation can be performed using Newton–Raphson or a method that does not require explicit derivatives. Assuming finite fourth moments, Weiss (1986) showed that the ML estimates are consistent and asymptotically normally disturbed. Many commercial statistical softwares such as the SAS now provide capabilities for ARCH modeling.

Diagnostic checking of the fit of ARCH models using standardized squared residual autocorrelations was considered in Li and Mak (1994). A fast method of detecting ARCH is by means of the port-manteau test of McLeod and Li (1983) using residuals from an autoregressive moving average model. As an illustration, we consider the daily closing price of the Hong Kong Hang Seng Index in the year 1980. The data are transformed by taking natural logarithm and differenced once to achieve stationarity. The transformed data R_t are called the returns of the index. There are 245 observations. The sample autocorrelations of R_t in **Figure 1** show basically no noticeable dependence structure in R_t itself. However, the sample autocorrelations of R_t^2 in **Figure 2** show a very strong dependence structure for R_t^2 suggesting the presence of an ARCH structure. Based on the partial autocorrelations of R_t^2 we consider an ARCH model of order 7 for R_t. Using the method of ML we have the following result:

$$R_t = \sqrt{h_t}a_t$$

Figure 1 Sample autocorrelations of R_t.

with

$$h_t = 0.00012 + 0.3997R_{t-1}^2 + 0.13506R_{t-2}^2 + 0.12798R_{t-3}^2 + 0.15475R_{t-6}^2 + 0.28445R_{t-7}^2.$$

As reported in Li and Mak (1994) the sample autocorrelations of R_t^2 standardized by h_t show no further significant values and the above ARCH model is thus considered adequate.

Bollerslev (1986) generalized the ARCH(r) model to the GARCH(r, s) model, where

$$X_t = \sqrt{h_t}a_t$$

and

$$h_t = \alpha_0 + \sum_{i=1}^{r}\alpha_i X_{t-i}^2 + \sum_{i=1}^{s}\beta_i h_{t-i} \qquad [12]$$

with $\alpha_0 > 0$, $\alpha_i \geq 0$, $\beta_i \geq 0$.

The condition for covariance stationarity is $\sum_{i=1}^{r}\alpha_i + \sum_{i=1}^{s}\beta_i < 1$. Estimation of model 12 is similar to that of the ARCH models and exogeneous variables can be easily included. The second order moment properties of X_t^2 are like those of an ARMA(p, s) where $p = \max(r, s)$. The GARCH models have been very popular in the modeling of volatility in the finance literature. Bollerslev et al., (1992, 1994) provided two extensive reviews of the GARCH literature. Gourieroux (1997) and Bera and Higgins (1995) gave a more advanced coverage including multivariate ARCH models. The work edited by Engle (1995) has included many of the important contributions to the ARCH literature.

Models with Long Memory

Many stationary dynamical systems under model 4 in fact lead to $\{X_t\}$ which are short memory in the sense that the moduli of the autocovariances $C(k) = \mathrm{cov}(X_t, X_{t-k})$, $k = 1, 2, \ldots$ sum to a finite value. However, in some applications it is possible that $\sum_{k=0}^{\infty}|C(k)| = \infty$. A time series with this property is said to have the long memory property. One approach to modeling the long memory property is by means of fractional differencing. Suppose that B is the backshift operator, $BX_t = X_{t-1}$. Then a long memory dynamical system can be constructed by considering the process satisfying (Granger and Joyeux, 1980),

$$(1-B)^d X_t = a_t \qquad [13]$$

where d is a non-integer and

$$(1-B)^d = \sum_{k=0}^{\infty}\binom{d}{k}(-1)^k B^k$$

The process is stationary and invertible if $-1/2 < d < 1/2$ and possesses the long memory property if $0 \leq d < 1/2$. The fractionally integrated autoregressive moving average (FARIMA) process of order (p, d, q) satisfies Hosking (1981), and Granger and Joyeux (1980),

$$\phi(B)(1-B)^d X_t = \theta(B)a_t \qquad [14]$$

Figure 2 Sample autocorrelations of R_t^2.

where

$$\phi(B) = 1 - \phi_1 B \ldots - \phi_p B^p, \theta(B) = 1 - \theta_1 B \ldots - \theta_q B^q$$

and d is as in eqn [13]. It is further assumed that ϕ(B) and θ(B) have all roots outside the unit circle, which implies that X_t is stationary and invertible. Hosking (1981) showed that the autocovariances $C(k)$ of X_t are of the order $|k|^{2d-1}$ so that unlike ARMA process, $C(k)$ decays hyperbolically rather than exponentially. The spectral density $f(\lambda)$ of the process can be written in the form

$$f(\lambda) = \frac{\sigma_a^2}{2\pi}|1 - e^{i\lambda}|^{-2d} . \frac{\left|\theta\left(e^{i\lambda}\right)\right|^2}{\left|\phi\left(e^{i\lambda}\right)\right|^2}, \qquad [15]$$

where σ_a^2 is the variance of a_t. Beran (1994) contained a detailed exposition of the subject while Brockwell and Davis (1991) gave a good introduction including least squares and ML estimation.

Second Generation Models

Tong (1990) suggested that many of the aforementioned models can be combined to form new nonlinear models. He called these second generation models. For example, Tong (1990) suggested the possibility of a threshold AR model with ARCH. His idea was applied to real data by Li and Lam (1995). Li and Li (1996) extended this further to the double threshold ARCH or DTARCH models. These models allow for a threshold structure in both the conditional mean and the conditional variance. Clearly the number of possibilities is unlimited and one can consider models like double threshold long memory models with GARCH.

Discrete Valued Time Series

In many applications, the time series under consideration may be integer valued or may possess a discrete marginal distribution. An obvious approach to generate discrete random variables is by means of a possibly higher order Markov chain. Such is the approach of Raftery (1985) and Pegram (1980). A more elegant approach is that of McKenzie (1986) which is based on the method of thinning. Böckenholt (1999) considered a mixed integer-valued autoregressive Poisson regression with an application to category purchase data. Discrete-valued time series may also be generated using a conditional generalized linear model as in Zeger and Qaqish (1988). Li (1991) considered the goodness of fit problem for this approach. The recent work of MacDonald and Zucchini (1997) gave a valuable and timely survey of this vast area.

Conclusion

There is certainly a myriad of nonlinear models to consider when one decides to leave the restriction of the linear domain. What models to consider clearly depends on the goal and nature of the investigation. In many cases, flexibility in describing a variety of features such as time irreversibility, limit cycles, and autocorrelation structure is an important criterion. The availability of handy softwares is another important factor as illustrated by the examples considered. In many cases, automatic model selection criteria such as AIC and BIC, appropriately used, help to reduce the number of choices to a manageable few and so do model checking methods. The final test of a model in time series, in many applications is, of course, its ability to predict the future accurately.

Abstract

Time series data in business, economics, environment, medicine, and other scientific fields tend to exhibit patterns such as trends, seasonal fluctuations, irregular cycles, and occasional shifts in level or variability. The objectives of analyzing such series are often to extrapolate the dynamic pattern in the data for forecasting future observations, to estimate the effect of known exogenous interventions, and to detect unsuspected interventions. This article sketches some useful methods for achieving these objectives. Serial dependence in time series data can often be adequately approximated by a linear dynamic model. We focus on the development of a class of parsimonious linear models, the mixed autoregressive moving average (ARMA) models, which are widely used to represent stationary and nonstationary series. For unit root nonstationarity, this leads to the class of autoregressive integrated moving average (ARIMA) models. An iterative model building approach proposed by Box and Jenkins, consisting of tentative model specification, efficient estimation, and diagnostic checking, is discussed and illustrated by an actual example. The ARIMA models are extended to represent seasonal patterns in the data, and to include an additive component for the dynamic effect of interventions. The correspondence between the ARMA models and the GARCH models commonly used in analyzing financial time series data with heterogeneous variances is illustrated. Finally, some extensions to nonlinear time series models, in particular the threshold autoregressive models, are presented.

Objectives of Time Series Analysis

Data in business, economics, engineering, environment, medicine, and other fields of scientific investigations are often collected in regular time intervals. Such data are called time series. Examples are hourly temperature readings, daily stock prices, weekly traffic volume, monthly money supply, quarterly GNP (gross national product), annual growth rates, etc. Time series data tend to exhibit patterns such as trends, seasonal fluctuations, irregular cycles, and occasional shifts in level or variability. The data are, therefore, dynamically or serially correlated.

In practice, the main objectives of analyzing time series are: (1) to ascertain and extrapolate the dynamic pattern in the data for forecasting future observations, (2) to assess the effect of exogenous interventions known to have occurred at given time points, and (3) to detect unknown and unsuspected interventions. For example, one may use the available weekly sales of frozen orange juice over the last 3 years to forecast the sales for the next 6 weeks and to assess the impact of a major promotion campaign initiated 4 weeks ago. As another example, an air pollution data analyst may discover a sudden drop in the time series of monthly ambient carbon monoxide concentration level and find out that the drop can be attributed to an unsuspected change in the measuring instrument. We here sketch some useful methods for achieving these objectives.

Stochastic Structure of Time Series Observations

Let $\ldots, t-1, t, t+1, \ldots$ denote equally spaced time points and y_t the observation at time t. The probability model generating the series $\{y_t\}$ is called a *stochastic process*, and the observed time series data are then a realization of the process. It is important to note a key distinction between time series observations and observations generated from designed experiments. For time series, there is usually one and only one realization at a given time point t, while because experiments can be repeated, there can be many realizations under the 'same' experimental conditions. Thus, statistical inference on time series depends critically on the nature of the serial dependence of the stochastic process under study.

Stationary versus Nonstationary Processes

When the joint probability distribution of any k observations $y_{t+1}, \ldots, y_{t+k}$ from a stochastic process remains the same for different values of t, the process is said to be 'stationary.' In practice, this means that there is a state of equilibrium in which the overall behavior of the time series stays roughly the same over time. When this condition does not hold, the series is said to be nonstationary. The theory of stationary processes has been well developed and plays an important role in time series analysis. Although many of the time series encountered in practice exhibit a nonstationary behavior, it is frequently the case that a suitable transformation such as differencing the data will render them stationary so that the theory of stationary processes can be applied.

To illustrate, Figure 1 shows the time series of monthly interest rates of 90-day Treasury bills from January 1985 to December 1993, and Figure 2 the series of month to month changes of the rates (first differences). The interest rate series exhibits a drifting or wandering behavior without a stable level. On the other hand, the series of the first differences seems to fluctuate about a fixed mean level with constant variance over the observational period. This example shows that a drifting nonstationary series can be transformed into a stationary one

Figure 1 Monthly interest rates of 90-day Treasury bills, 1985–93.

Figure 2 Month to month changes of the interest rates.

by the differencing operation. In fact, financial time series such as stock prices, prices of derivatives, and exchange rates often behave in this manner.

Linear Dynamic Models

The serial dependence in the time series $\{y_t\}$ can often be adequately approximated by a linear model of the form.

$$y_t = c + \pi_1 y_{t-1} + \pi_2 y_{t-2} + \ldots + \pi_j y_{t-j} + \ldots + a_t \qquad [1]$$

where c is a constant, π_1, π_2,… are parameters relating y_t linearly to its past values, and a_t is the innovation or shock hitting the system at time t. It is commonly assumed that $\{a_t\}$ is a series of identically and independently distributed normal random variables with zero mean and common variance σ^2. The linear dynamic model in eqn [1] can also be expressed in the alternative form

$$y_t = c^* + a_t + \psi_1 a_{t-1} + \psi_2 a_{t-2} \ldots + \psi_j a_{t-j} + \ldots \qquad [2]$$

where c^* is a constant, and the two parameter sets (π_1, π_2,…) and (ψ_1, ψ_2,…) are functionally related. In eqn [2] ψ_j measures the effect of the shock a_{t-j} hitting the system j periods ago on the observation y_t. The ψ_j's are called impulse responses or the memory of the system. The two representations in eqns [1] and [2], although equivalent, highlight two distinctive features of the linear system.

For forecasting future observations at a given time origin T, let us consider first the next observation y_{T+1}. By putting $t = T + 1$ in eqn [1], it is easy to show that the best (minimum mean squared error) predictor of y_{T+1} is a linear combination of the available observations $(y_T, y_{T-1}, \ldots)$, $\widehat{y}_{T+1} = c + \pi_1 y_T + \pi_2 y_{T-1} + \ldots$, and the associated forecast error is simply $y_{T+1} - \widehat{y}_{T+1} = a_{T+1}$ having variance σ^2. It is straightforward to deduce from eqn [1] best predictors of observations y_{T+l}, $\ell = 2, 3, \ldots$ periods ahead as linear functions of (y_T, y_{T-1},…) and their associated forecast errors as linear combinations of future shocks (a_{T+1},…, $a_{T+\ell}$).

ARMA and ARIMA Models

In reality, the model in eqn [1] or [2] is not known and has to be built from available data. Since y_t can in principle relate to its remote past, or to the remote past of a_t, for parsimony it is useful to make the π's or ψ's functions of a small set of parameters which can then be accurately estimated from the data. A class of such models originally proposed by Yule and Slutsky in the 1920s is the (mixed) autoregressive moving average (ARMA) models of orders (P, Q).

$$y_t - \phi_1 y_{t-1} - \ldots - \phi_P y_{t-P} = c + a_t - \theta_1 a_{t-1} - \ldots - \theta_Q a_{t-Q} \qquad [3]$$

This class of models has been found useful to represent a variety of stationary, nonstationary, and seasonal time series in diverse scientific fields. By straightforward substitutions, one can readily deduce the π's and ψ's in eqns [1] and [2] as functions of the finite parameter set (ϕ_1,…, ϕ_P; θ_1,…, θ_Q) in eqn [3].

To illustrate, consider first the case ($P = 0$, $Q = 1$) so that $y_t = c + a_t - \theta_1 a_{t-1}$, which is the first-order moving average model. This model says that when the shock a_t hits the system at time t it will affect not only the observation y_t but also the next observation y_{t+1} (since $y_{t+1} = c + a_{t+1} - \theta_1 a_t$). Thus, the effect of the shock a_t will last over the two periods t and $t + 1$ and dissipate afterward. This short memory stationary model has been found useful to represent time series of various financial returns.

Consider next the case ($P = 1$, $Q = 0$) so that the model is $y_t = c + \phi_1 y_{t-1} + a_t$, which is the first-order autoregressive model frequently discussed in the economics literature. This model is stationary when $|\phi_1| < 1$. It can be expressed in the alternative memory form $y_t = c^* + a_t + \phi_1 a_{t-1} + \phi_1^2 a_{t-2} + \mathrm{L}$ showing that the effect or memory of the shock a_t will persist over many periods but will gradually dissipate when the model is stationary. In this case, the l-step ahead forecast will converge to the mean level of the series as the horizon l increases. For ($c = 0$, $\phi_1 = 1$), this model is a nonstationary 'random walk' widely believed to be appropriate for stock prices in an 'efficient market.'

As a final illustration, for ($c = 0$, $P = Q = 1$, $\phi_1 = 1$) we have the model $y_t - y_{t-1} = a_t - \theta_1 a_{t-1}$. For this model, the left-hand side is the first difference of y_t implying that the series $\{y_t\}$ is nonstationary but the first difference series is stationary and follows the first-order moving average model. At the time origin T, the l-step ahead predictor is, for all $\ell \geq 1$, $\widehat{y}_{T+\ell} = (1 - \theta_1) y_T + \theta_1 (1 - \theta_1) y_{T-1} + \theta_1^2 (1 - \theta_1) y_{T-2} + \ldots$, which is an exponentially weighted average of current and past observations. Predictors of this kind which give more weight to recent information and less and less weight to information from the remote past seem intuitively

appealing because time series data, especially in business and economics, tend to exhibit nonstationary behavior over time. As a result, the 'exponential smoothing' forecast discussed here has been the most widely applied forecasting technique in practice. It will be seen later that the Treasury bills data shown in Figure 1 can be adequately represented by this model.

To sharpen the distinction between stationary and nonstationary models, we can express the ARMA (P, Q) models in eqn [3] alternatively as.

$$\begin{aligned}\nabla^d y_t - \varphi_1 \nabla^d y_{t-1} - \ldots - \varphi_p \nabla^d y_{t-p} \\ = c + a_t - \theta_1 a_{t-1} - \ldots - \theta_q a_{t-q}\end{aligned} \quad [4]$$

where $d = 0, 1, 2, \ldots, \nabla^d y_t$ is the dth difference of y_t (i.e., $\nabla^d y_t = y_t$ if $d = 0$, $\nabla^d y_t = y_t - y_{t-1}$ if $d = 1$, $\nabla^d y_t = y_t - 2y_{t-1} + y_{t-2}$ if $d = 2$, etc.), $P = p + d, Q = q$, the two parameter sets $(\phi_1, \ldots, \phi_P)$ and $(\varphi_1, \ldots, \varphi_p)$ are functionally related, and we shall assume that the ARMA model for $\nabla^d y_t$ is stationary. This is saying that the time series $\{y_t\}$ is such that its dth difference $\nabla^d y_t$ is stationary and follows a mixed autoregressive moving average model. For $d = 0$, y_t itself is stationary; and for $d > 0$, y_t is nonstationary. The models in eqn [4] are called autoregressive integrated moving average (ARIMA) models of orders (p, d, q) for the time series y_t. Here d signifies the order of differencing to make the transformed series stationary, p is the number of lagged values of $\nabla^d y_t$, and q is the number of lagged terms of a_t in the model.

It should be noted that for the ARIMA models in eqn [4], the nonstationarity of the series y_t is solely accounted for by the difference operation $\nabla^d y_t$. While this is not the only kind of nonstationarity in the ARMA models in eqn [3], we shall, however, focus primarily on this class of models.

Model Building

To build an ARMA or ARIMA model for the data at hand, Box and Jenkins (1976) have proposed an iterative approach consisting of (a) tentative model specification, (b) efficient estimation, and (c) diagnostic checking. This approach has been widely adopted and in fact has revolutionized the use of time series models for forecasting in practice.

In the tentative specification phase, the goal is to employ computationally simple techniques to narrow down the range of parsimonious models worthy of more detailed further study. Techniques such as the sample autocorrelation function (SACF) and sample partial autocorrelation function (SPACF) have been widely used. The SACF can help determine the order of differencing needed to make the transformed series stationary and pin down the order of a moving average model for stationary series. The SPACF, on the other hand, is useful to help decide the order of a stationary autoregressive model. The more recently proposed sample extended autocorrelation function (SEACF, see Tsay and Tiao (1984)) makes it possible to specify directly the orders of an ARMA (P, Q) model, stationary or nonstationary, and hence simplifies the procedure for model specification. In this case, the question of stationarity will be answered at the estimation stage.

Once a model is tentatively entertained, the parameters can then be efficiently estimated by the method of maximum likelihood. In addition to standard tests on the statistical significance of parameter estimates, unit root tests may provide a useful tool here to help determine the order of nonstationarity in the series if needed. Finally, residuals calculated from the fitted model are then subject to various diagnostic checks to determine the overall adequacy of the entertained model and to search for directions of improvement. Of particular importance are procedures to detect the existence of autocorrelations in the residuals, outliers and structural changes such as level shifts, variance changes, and nonlinearities.

To illustrate this model building approach, we consider the monthly interest rate data introduced earlier. Table 1 shows the SACF of the series y_t, the SACF and SPACF of the differenced series ∇y_t, and the SACF of the residuals $\hat{a}_t$ for lags 1–12.

In each of the four panels in Table 1, the first row gives the sample correlation values and the second their associated estimated standard errors. We now discuss tentative model specification. First, the persistently high values of the SACF of y_t over long lags suggest that the series is nonstationary, leading to considering the first difference of the series. Second, the SACF of ∇y_t has only one large value at lag 1, and this 'cutting off' property strongly indicates that a simple first-order moving average model would be adequate for the differenced series. On the other hand, the pattern of the SPACF of ∇y_t, showing two large values at lag 1 and lag 3, would suggest a more complex model.

Table 1 SACF and SPACF for the interest rate data

1.	SACF of y_t												
	Lags 1–12	0.97	0.94	0.89	0.85	0.81	0.77	0.73	0.68	0.64	0.59	0.53	0.48

3.	SPACF of ∇y_t												
	Lags 1–12	0.46	−0.18	0.22	−0.05	0.07	0.03	0.01	0.08	0.06	−0.02	0.03	−0.11
	ST.E.	0.10	0.10	0.10	0.10	0.10	0.10	0.10	0.10	0.10	0.10	0.10	0.10
	SACF of $\hat{a}_t$												
	Lags 1–12	0.00	0.03	0.07	0.09	−0.00	0.08	0.03	0.03	0.11	0.02	0.03	0.02
	ST.E.	0.10	0.10	0.10	0.10	0.10	0.10	0.10	0.10	0.10	0.10	0.10	0.10

Table 2 Simplified SEACF for the interest rate data

($Q \rightarrow$)	0	1	2	3	4	5	6	7	8	9	10	11	12
($P = 0$)	X	X	X	X	X	X	X	X	X	X	X	O	O
($P = 1$)	X	O	O	O	O	O	O	O	O	O	O	O	O
($P = 2$)	X	X	O	O	O	O	O	O	O	O	O	O	O
($P = 3$)	X	X	O	O	O	O	O	O	O	O	O	O	O
($P = 4$)	O	X	O	O	O	O	O	O	O	O	O	O	O
($P = 5$)	X	O	X	O	O	O	O	O	O	O	O	O	O
($P = 6$)	X	O	O	O	O	O	O	O	O	O	O	O	O

Consequently we are led to consider the ARIMA (0, 1, 1) model.

$$\nabla y_t = a_t - \theta_1 a_{t-1} \qquad [5]$$

The above mode of model specification, while widely adopted in practice, has several drawbacks. First, judgment of whether to difference the data based on 'persistently high values of SACF' can often be difficult in practice. Second, for $d \geq 2$, at least three cycles of SACF and SPACF are needed before a model can be determined. Third, both SACF and SPACF are not designed to help specify stationary mixed ARMA (P, Q) models. The SEACF procedure is designed to address these difficulties. Table 2 gives the simplified SEACF for the interest rate data. In this two-way table, the rows correspond to the AR orders P and the columns the MA orders Q. An entry 'X' signifies that the sample estimate is over twice its estimated standard error in magnitude and a '0' otherwise. The goal is to search for a triangle of 0's just like the one shown in Table 2, and the coordinates of the vertex give the AR and MA orders. In our case, we have clear indication of an ARMA (1, 1) model.

$$y_t - \phi_1 y_{t-1} = c + a_t - \theta_1 a_{t-1} \qquad [6]$$

which reduces to the model in eqn [5] when $\phi_1 = 1$ and $c = 0$. The estimation results for both models in eqns [5] and [6] are summarized in Table 3. The values in parentheses are the associated estimated standard errors of the estimates. The results $\widehat{\phi}_1 \cong 1$ and $\widehat{c} \cong 0$ clearly show that the fitted models eqns [5] and [6] are essentially identical. Thus, instead of making the decision to difference the data series at the tentative model specification stage, the same result can be obtained at the estimation phase which seems more appealing. To provide a partial check of the adequacy of the model, the bottom panel of Table 1 shows the SACF of the residuals $\hat{a}_t$'s from the model in eqn [5]. All the sample autocorrelations are very small, indicating no dynamic pattern left in the residuals. Some additional residual diagnostics including the Box–Ljung statistic and an iterative outlier test have also been performed without revealing any serious model inadequacy. The fitted model can then be used to predict future observations if desired.

Table 3 Estimation results for the interest rate data

	$\widehat{\phi}_1$	$\widehat{c}$	$\widehat{\theta}_1$	$\widehat{\sigma}$
Model (5)			−0.597 (0.077)	0.198
Model (6)	0.993 (0.017)	−0.002 (0.107)	−0.592 (0.078)	0.196

Seasonal ARIMA Models

Business, economic, and atmospheric time series data often exhibit a strong, but not necessarily deterministic, seasonal behavior. It seems natural to think that the seasonal pattern arises simply because observations at the same time point of the year are dynamically related across the years. For monthly data, this means that observations 12, 24,… periods apart are correlated. Just as the class of ARIMA (p, d, q) models represent the dependence of observations in successive periods (months), we may construct similar models to account for dynamic dependence of observations in the same month of successive years. As an illustration, corresponding to the regular ARIMA (0, 1, 1) model in eqn [5], we may consider a seasonal model of the from $\nabla_{12} y_t = e_t - \Theta_{12} e_{t-12}$, where $\nabla_{12} y_t = y_t - y_{t-12}$ is the seasonal difference and e_t is the noise term. To account for both seasonal dependence as well as month to month dependence, we may make e_t to follow the ARIMA (0, 1, 1) model $\nabla e_t = a_t - \theta_1 a_{t-1}$. Together, we have that.

$$\nabla\nabla_{12} y_t = a_t - \theta_1 a_{t-1} - \Theta_{12}(a_{t-12} - \theta_1 a_{t-13}) \qquad [7]$$

where $\nabla\nabla_{12} y_t = y_t - y_{t-1} - (y_{t-12} - y_{t-13})$ is the double, regular and seasonal, difference of y_t. This 'doubly' exponential smoothing model, proposed by Box and Jenkins and motivated by their analysis of airline passenger data, has been widely used to present a variety of seasonal time series in practice. It is known as the 'airline model.' Similar extensions are readily obtainable for other ARIMA models.

Intervention Analysis and Outlier Detection

Time series observations are often subject to the influence of special events, or interventions, that occurred at known time points. Examples are the outbreak of armed conflicts, natural disasters, changes in fiscal policy, and major sales promotions. It has been found useful to employ linear dynamic models of the form.

$$Y_t - \delta_1 Y_{t-1} - \ldots - \delta_r Y_{t-r} = \omega_0 x_t - \ldots - \omega_s x_{t-s} \qquad [8]$$

where x_t is an indicator (dummy) variable for an intervention and Y_t represents its dynamic impact on the time series observations. This class of models can accommodate a very wide variety of dynamic patterns including isolated large values, level shifts, trend, oscillations, and cycles. We can write the model of the observations as the sum of the intervention component Y_t and a noise component N_t, $y_t = Y_t + N_t$, where

N_t follows an ARMA model of the form in eqn [3]. The parameters in the intervention and the noise components can then be jointly estimated to quantify the effects of these two components.

When the time of occurrence of interventions is not known or the interventions themselves are unsuspected, we have the problem of detecting unusual events or 'outliers' in time series. Estimation procedures developed for interventions can be readily adapted to become iterative procedures for outlier detection, and these methods, especially those for detecting isolated large values and level shifts, have been commonly adopted as part of diagnostic checking.

Time Series with Heterogeneous Variances

The ARMA model in eqn [3] supposes that the variance σ^2 of the innovation a_t stays constant over time. In reality, this variance homogeneity assumption is often violated, especially in highly disaggregated financial data such as hourly stock returns or exchange rates where clusters of high volatility tend to occur. Several models have been developed to describe this kind of phenomenon. Denoting a_t^2 as the variance of a_t, one may employ a random step-change model in which there is a nonzero probability λ that σ_t^2 may change at any given point of time. Alternatively, one may relate σ_t^2 to past values of a_t^2 and itself. In particular, the model.

$$\sigma_t^2 = \alpha_0 + \alpha_1 \alpha_{t-1}^2 + \beta_1 \alpha_{t-1}^2 \qquad [9]$$

which is called the generalized autoregressive conditional heteroscedastic (GARCH) model of orders (1, 1) has been extensively used in the analysis of financial time series. Now writing $a_t^2 = \sigma_t^2 + u_t$, the above model can be alternatively expressed as

$$a_t^2 = \alpha_0 + (\alpha_1 + \beta_1) a_{t-1}^2 + u_t - \beta_1 u_{t-1} \qquad [10]$$

It can be readily shown that the u_t's have zero mean and common variance, and are uncorrelated. Thus the model in eqn [10] has exactly the same autocovariance structure as an ARMA (1, 1) model in a_t^2. The above correspondence is readily extended to higher order models. Thus the GARCH models can be viewed as an interesting extension of the ARMA structure to the squared innovations a_t^2's.

Nonlinear Time Series Models

There is an extensive literature on nonlinear time series models where y_t is related to its past values more generally by a nonlinear function. Such models are necessarily more complex, but they can represent phenomena such as time irreversibility and limit cycles that cannot be adequately described by linear models. For example, it is well known that the dynamic behavior of economic indicators such as the GNP or the unemployment rate during a recession is quite different from that when the economy is expanding. To describe this kind of nonhomogeneous behavior, one may employ a piecewise linear model for different regimes of economic activity. To illustrate, let y_t represent the quarterly change in GNP. We may postulate a model such that.

$$y_t = \begin{cases} c^{(1)} + \phi^{(1)} y_{t-1} + a_t^{(1)}, & \text{if} \quad y_{t-1} < 0 \text{ and } y_{t-2} < 0 \\ c^{(2)} + \phi^{(2)} y_{t-1} + a_t^{(2)}, & \text{if} \quad \text{otherwise} \end{cases} \qquad [11]$$

where $c^{(1)} \neq c^{(2)}$, $\phi^{(1)} \neq \phi^{(2)}$, and $a_t^{(1)}$ and $a_t^{(2)}$ have unequal variances. In eqn [11] the regime ($y_{t-1} < 0$ and $y_{t-2} < 0$) represents a period of economic decline, and the model says that the dynamic behavior of y_t is different for the two regimes. This model is a special case of a class, known as the threshold autoregressive models, which have been used for time series data in atmospheric sciences, economics, and other scientific fields.

Further Reading

The reader interested in a deeper understanding of the basic concepts and methods of time series analysis may consult the books by Box et al. (1994), Brockwell and Davis (1996), Shumway and Stoffer (2000), and Wei (1990), and the book edited by Pena et al. (2001) which also contains several chapters on multivariate ARMA models. For further details on the GARCH models and the general topic of heterogeneous variances and volatility clustering in economic time series, see Hamilton (1994). Nonlinear time series models are discussed in Priestley (1988) and Tong (1990). Finally, for multivariate extension of linear time series models, the reader may study the books by Lutkepohl (1993), Reinsel (1993) and Reinsel and Velu (1998).

Abstract

An overview of results for the cointegrated vector autoregressive model for nonstationary $I(1)$ variables is given. The emphasis is on the analysis of the model and the tools for asymptotic inference. These include: formulation of criteria on the parameters, for the process to be nonstationary and $I(1)$, formulation of hypotheses of interest on the rank, the cointegrating relations and the adjustment coefficients. A discussion of the asymptotic distribution results that are used for inference. The results are illustrated by a few examples. A number of extensions of the theory are pointed out.

Introduction

The term cointegration was defined by Granger (1983) as a formulation of the phenomenon that nonstationary processes can have linear combinations that are stationary. It was his investigations of the relation between cointegration and error correction that brought modeling of vector autoregressions with unit roots and cointegration to the center of attention in applied and theoretical econometrics; see Engle and Granger (1987).

During the last 30 years, many have contributed to the development of theory and applications of cointegration. The account given here focuses on theory, more precisely on likelihood-based theory for the vector autoregressive model; see Johansen (1996). By building a statistical model as a framework for inference, one has to make explicit assumptions about the model used and hence has a possibility of checking the assumptions made before conducting inference.

We start with some examples of cointegration.

Example 1: As a simple economic example of the main idea in cointegration, consider 229 observations of US monthly interest rates in the period 1987:1 to 2006:1, which defines the period when Greenspan was the chairperson of the Federal Reserve System. The data are taken from IMF's financial database and consist of the 6 months treasury bill rate and the 3 years bond rate, denoted by i_{6m} and i_{3y}, respectively. In **Figure 1** we plot the two interests rates and their spread $i_{6m} - i_{3y}$. The expectations hypothesis implies that these interest rates should be equal up to a constant, $i_{3y} = i_{6m} + c$, and such a relation is not found in data. We can formulate it instead as their spread being stationary around a constant, possibly zero. This is an example of the formulation of an economic regularity as a cointegrating relation and we want below to analyze a statistical model, which allows such a formulation.

As simple examples of models for processes of this nature, we first consider a model for a random walk and a stationary process. Throughout we consider the sequence of p-dimensional errors ε_t, $t = 1,\ldots, T$, which are independent and identically distributed with mean zero and variance matrix, Ω.

Example 2: (Autoregressive processes) (**Figure 2**) Let $x_t = (y_t, z_t)'$ be given by the equations for $t = 1,\ldots,T$

$$y_t = y_{t-1} + \varepsilon_{yt} \quad [1]$$

$$z_t = \rho z_{t-1} + \varepsilon_{zt} \quad [2]$$

here $-1 < \rho < 1$. It is seen that $y_t = y_0 + \varepsilon_{y1} + \ldots + \varepsilon_{yt}$ and that $E(y_t|y_0) = y_0$ and $Var(y_t|y_0) = t\Omega$, so the variance is increasing and the process is nonstationary. We also find $z_t = \rho^t z_0 + \sum_{i=0}^{t-1}\rho^i\varepsilon_{z,t-i}$ which implies that $E(z_t|z_0) = \rho^t z_0$ and $Var(z_t|z_0) = \sigma_z^2\sum_{i=0}^{t-1}\rho^{2i} \to \sigma_z^2\sum_{i=0}^{\infty}\rho^{2i} = \sigma_z^2/(1-\rho^2)$. We can make z_t stationary by choosing $z_0 = \sum_{i=0}^{\infty}\rho^i\varepsilon_{z,-i}$ and then $z_t = \sum_{i=0}^{\infty}\rho^i\varepsilon_{z,t-i}$. We call y_t an $I(1)$ process and z_t an $I(0)$ process, see section Integration and Cointegration.

Figure 1 A plot of 229 monthly observations of the 6 months treasury bill rate and the 3 years bond rate and their spread $i_{6m} - i_{3y}$. Note the nonstationary behavior of the interest rates and the much more stationary spread, see Example 1.

Figure 2 Three examples of $AR(1)$ processes. Each plot has 100 observations. The first two are stationary with $\rho = 0.1$ and $\rho = 0.5$, and the last is a random walk with $\rho = 1$, see Example 2.

Next we give a model for nonstationary variables that are cointegrated, using the notation, $\Delta x_t = x_t - x_{t-1}$.

Example 3: (Cointegrated processes) A bivariate process is given for $t = 1,\ldots,T$ by the equations

$$\begin{aligned}\Delta x_{1t} &= \alpha_1(x_{1t-1} - x_{2t-1}) + \varepsilon_{1t} \\ \Delta x_{2t} &= \alpha_2(x_{1t-1} - x_{2t-1}) + \varepsilon_{2t}\end{aligned} \qquad [3]$$

Subtracting the equations, we find that the process $y_t = x_{1t} - x_{2t}$ is autoregressive, see [2] and stationary if $\rho = 1 + \alpha_1 - \alpha_2$ satisfies $|\rho| < 1$, and the initial value is given by its invariant distribution. Similarly we find that $s_t = \alpha_2 x_{1t} - \alpha_1 x_{2t}$ is a random walk, see [1], so that the process $x_t = (x_{1t}, x_{2t})'$ is given by

$$x_{1t} = \frac{s_t - \alpha_1 y_t}{\alpha_2 - \alpha_1} \quad \text{and} \quad x_{2t} = \frac{s_t - \alpha_2 y_t}{\alpha_2 - \alpha_1}$$

This shows that when $|1 + \alpha_1 - \alpha_2| < 1$, x_t is $I(1)$, $x_{1t} - x_{2t}$ is stationary, and $\alpha_2 x_{1t} - \alpha_1 x_{2t}$ is a random walk $\sum_{i=1}^{t}(\alpha_2\varepsilon_{1i} - \alpha_1\varepsilon_{2i})$, so that x_t is a cointegrated $I(1)$ process with cointegration vector $\beta' = (1, -1)$. We call s_t a common stochastic trend and α, the adjustment coefficients (Figure 3).

Three Approaches to Cointegration

There are at present three different ways of modeling the linear cointegration idea in a parametric statistical framework. To illustrate the ideas they are formulated in the simplest possible cases, leaving out deterministic terms.

Regression Formulation

The multivariate process, $x_t = (x'_{1t}, x'_{2t})'$ of dimension $p = p_1 + p_2$ is given by the regression equations

$$\begin{aligned}x_{1t} &= \gamma' x_{2t} + \varepsilon_t \\ \Delta x_{2t} &= \varepsilon_{2t}\end{aligned}$$

This model implies that x_{2t} is a nonstationary random walk, and $x_{1t} - \gamma' x_{2t}$ gives p_1 stationary linear combinations. Hence, in this case, the cointegration rank of x_t is p_1, see section Integration and Cointegration. The first estimation method used in this model is least squares regression, Engle and Granger (1987), which is shown to give a superconsistent estimator by Stock (1987). This estimation method gives rise to residual based tests for cointegration. It was shown by Phillips and Hansen (1990) that, for a more general error term, a modification of the regression estimator gives useful methods for inference on coefficients of cointegration relations; see also Phillips (1991).

Autoregressive Formulation

In the rest of this contribution we focus on the autoregressive formulation of the p-dimensional process, x_t, defined by the equations

$$\Delta x_t = \alpha\beta' x_{t-1} + \varepsilon_t$$

where α and β are $p \times r$ matrices of rank r. Under the condition that Δx_t is stationary, the solution is

$$x_t = C\sum_{i=1}^{t}\varepsilon_i + \sum_{i=0}^{\infty} C_i\varepsilon_{t-i} + A \qquad [4]$$

where $C = \beta_\perp(\alpha'_\perp\beta_\perp)^{-1}\alpha'_\perp$ and $\beta' A = 0$. Here $\beta_\perp$ is a full rank, $p \times (p - r)$, matrix so that $\beta'\beta_\perp = 0$. This formulation allows for modeling of both the long-run relations, $\beta' x$, and the adjustment, or feedback coefficient α, toward the attractor set $\{x : \beta' x = 0\}$ defined by the long-run relations. Models for different cointegration ranks are nested and the smallest, for $\alpha = \beta = 0$, corresponds to p random walks. The rank can be analyzed by likelihood ratio tests. Methods usually applied for this analysis are derived from the Gaussian likelihood function, which is discussed here; see also Johansen (1988, 1996), and Ahn and Reinsel (1990).

Figure 3 Two simulations of model [3] for cointegrated variables, see Example 3.

Unobserved Components Formulation

Let x_t be given by

$$x_t = \xi\eta' \sum_{i=1}^{t} \varepsilon_{1i} + \varepsilon_{2t}$$

where ε_{2t}, typically, is independent of ε_{1t}.

In this formulation too, hypotheses of different ranks are nested but in the opposite direction, and the smallest, for $\xi = \eta = 0$, corresponds to stationary processes. The parameters are linked to the autoregressive formulation by $\xi = \beta_\perp$ and $\eta = \alpha_\perp$, even though the linear process, $\sum_{i=0}^{\infty} C_i\varepsilon_{t-i}$, in [4] depends on the random walk part, so the unobserved components model and the autoregressive model are not the same. However, both adjustment and cointegration can be discussed in this formulation, and hypotheses on the rank can be tested. Rather than testing for unit roots, one tests for stationarity, which is sometimes a more natural formulation. Estimation is performed by the Kalman filter, and asymptotic theory of the rank tests has been worked out by Nyblom and Harvey (2000), see also Durbin and Koopman (2012).

The Model Analyzed in This Contribution

In the following we consider cointegration modeled by the cointegrated vector autoregressive (CVAR) model, $H(r)$, for the p-dimensional process x_t,

$$H(r) : \Delta x_t = \alpha(\beta' x_{t-1} + \gamma D_t) + \sum_{i=1}^{k-1} \Gamma_i \Delta x_{t-i} + \Phi d_t + \varepsilon_t \quad [5]$$

The terms D_t and d_t are deterministic terms like constant, trend, seasonal or intervention dummies. The matrices α and β are $p \times r$ where $0 \le r \le p$. In section Integration and Cointegration, conditions for the processes $\beta' x_t$ and Δx_t to be stationary around their means are given, and model [5] can then be formulated as

$$\begin{aligned}\Delta x_t - E(\Delta x_t) &= \alpha(\beta' x_{t-1} - E(\beta' x_{t-1})) \\ &\quad + \sum_{i=1}^{k-1} \Gamma_i(\Delta x_{t-i} - E(\Delta x_{t-i})) + \varepsilon_t\end{aligned}$$

This shows how the change of the process reacts to feedback from disequilibrium errors $\beta' x_{t-1} - E(\beta' x_{t-1})$ and $\Delta x_{t-i} - E(\Delta x_{t-i})$, via the short-run adjustment coefficients, α and Γ_i. The equation $\beta' x_t - E(\beta' x_t) = 0$ defines the long-run relations between the processes.

There are many surveys of the theory of cointegration; see for instance Watson (1994) and Stock (1994) or Johansen (2006, 2009), where the last two form the basis for the presentation here. The topic has become part of most textbooks in econometrics; see among others Banerjee et al. (1993), Hamilton (1994), Hendry (1995), and Lütkepohl (2006). For a general account of the methodology of the CVAR model with applications to the analysis of economic data, see Juselius (2006).

Linear Stationary Processes

We consider p-dimensional linear stationary processes

$$z_t = \sum_{i=0}^{\infty} C_i \varepsilon_{t-i}$$

which are well defined if the coefficient matrices satisfy the condition that $\sum_{i=0}^{\infty} tr^{1/2}(C_i' C_i) < \infty$, where the trace of a matrix, C, is $tr(C) = \sum_{i=1}^{p} C_{ii}$. If in [5] we consider $r = p$ we define the matrix $\Pi = \alpha\beta'$ and the matrix valued characteristic polynomial

$$\Psi(z) = (1-z)I_p - \Pi z - (1-z)\sum_{i=1}^{k-1} \Gamma_i z^i \quad [6]$$

with determinant $|\Psi(z)|$. The properties of the solution of [5] are determined by $\Psi(z)$. We define the roots $z_i, i = 1,\ldots,n$, as the

solutions of $|\Psi(z)| = 0$, and get, because $|\Psi(0)| = 1$, that $|\Psi(z)| = \prod_{i=1}^{n}(1 - z/z_i)$. The inverse characteristic polynomial is given by

$$\Psi(z)^{-1} = \frac{\mathrm{adj}(\Psi(z))}{\det\Psi(z)}, z \neq z_i$$

that is, the adjoint of $\Psi(z)$ divided by the determinant of $\Psi(z)$.

The function, $C(z) = \Psi(z)^{-1}$ has poles at the roots of the polynomial $|\Psi(z)|$, and the position of the poles determine the stochastic properties of the solution of [5]. We first mention a well-known result; see Anderson (1971).

Theorem 1: If the roots satisfy $|z_i| > 1$, then α and β have full rank $r = p$, and the coefficients of $\Psi^{-1}(z) = \sum_{i=0}^{\infty} C_i z^i$ are exponentially decreasing. Let $\mu_t = \sum_{i=0}^{\infty} C_i(\alpha\Upsilon D_{t-i} + \Phi d_{t-i})$. Then the distribution of the initial values of x_t can be chosen so that $x_t - \mu_t$ is stationary with moving average representation

$$x_t - \mu_t = \sum_{i=0}^{\infty} C_i \varepsilon_{t-i}$$

Thus the exponentially decreasing coefficients are found by simply inverting the characteristic polynomial if the roots are outside the unit disk. The matrices, C_i contain the impulse response coefficient of the process in the sense that a shock at time zero to variable k will have the effect, $(C_t)_{ik}$ at time t to variable i.

Integration and Cointegration

The basic definitions of integration and cointegration are given together with a moving average representation of the solution of the error correction model [5]. This solution reveals the stochastic properties of the solution, see Example 3.

If the roots of $|\Psi(z)| = 0$ are not greater than 1, the equations generate nonstationary processes of various types, and the coefficients are not exponentially decreasing. Still, the coefficients of $C(z) = \Psi^{-1}(z)$ determine the stochastic properties of the solution of [5].

Definition 1: If $\sum_{i=0}^{\infty} tr^{1/2}(C_i'C_i) < \infty$, the linear process $x_t - E(x_t) = \sum_{i=0}^{\infty} C_i \varepsilon_{t-i}$ is called $I(0)$ if $C(1) = \sum_{i=0}^{\infty} C_i \neq 0$ The process, x_t is called integrated of order 1, $I(1)$, if $\Delta x_t - E(\Delta x_t)$ is $I(0)$. If there is a vector $\beta \neq 0$ so that $\beta' x_t$ is stationary around its mean, then x_t is cointegrated with cointegration vector, β. The number of linearly independent cointegration vectors is the cointegration rank.

We consider the process given by [5] and the characteristic polynomial, $\Psi(z)$ defined in [6]. This has a unit root, if $\Psi(1) = -\Pi$ is singular, and by Theorem 1, the process is not stationary. A singular matrix Π of rank r can be expressed as $\Pi = \alpha\beta'$, where α and β are $p \times r$. We next formulate a condition for the process to be $I(1)$. We define $\Gamma = I_p - \sum_{i=1}^{k-1} \Gamma_i$.

Assumption 1: (The $I(1)$ condition) The $I(1)$ condition is satisfied if the roots, $|\Psi(z_i)| = 0$ satisfy $|z_i| > 1$ or $z_i = 1$ and it holds that

$$|\alpha_\perp' \Gamma \beta_\perp| \neq 0 \qquad [7]$$

Condition [7] is needed to avoid solutions that are integrated of order 2 or higher; see section Further Topics in Cointegration for references. For a process with one lag $\Gamma = I_p$, and [5] implies

$$\beta' x_t = (I_r + \beta'\alpha)\beta' x_{t-1} + \beta'\varepsilon_t$$

In this case the $I(1)$ condition is equivalent to the condition that $\beta' x_t$ is stationary, that is, the absolute value of the eigenvalues of $I_r + \beta'\alpha$ are less than 1, and in Example 2 this condition reduces to $|1 + \alpha_1 - \alpha_2| < 1$.

Example 3 presents a special case of the Granger Representation Theorem, which gives the moving average representation of the solution of the error correction model.

Theorem 2: (The Granger Representation Theorem) If $\Psi(z)$ has unit roots and the $I(1)$ condition is satisfied, then

$$(1 - z)\Psi(z)^{-1} = C(z) = \sum_{i=0}^{\infty} C_i z^i = C + (1 - z)C^*(z)$$

converges for $|z| \leq 1 + \delta$ for some $\delta > 0$. The matrix C is defined by

$$C = \beta_\perp (\alpha_\perp' \Gamma \beta_\perp)^{-1} \alpha_\perp'$$

The solution x_t of [5] has the moving average representation

$$x_t = C\sum_{i=1}^{t}(\varepsilon_i + \Phi d_i) + \sum_{i=0}^{\infty} C_i^*(\varepsilon_{t-i} + \Phi d_{t-i} + \alpha\Upsilon D_{t-i}) + A \qquad [8]$$

where A depends on initial values, so that $\beta' A = 0$.

This result implies that Δx_t and $\beta' x_t$ are stationary around their mean, so that x_t is a cointegrated $I(1)$ process with r cointegration vectors β and $p - r$ common stochastic trends $\alpha_\perp' \sum_{i=1}^{t} \varepsilon_i$.

One of the useful applications of the representation [8] is to investigate the role of the deterministic terms. Note that d_t cumulates in the process with a coefficient, $C\Phi$, but that D_t does not, because $C\alpha\Upsilon = 0$. A leading special case is the model with $D_t = t$, and $d_t = 1$, which ensures that any linear combination of the components of x_t is allowed to have a linear trend. Note that if $D_t = t$ is not allowed in the model, that is $\Upsilon = 0$, then x_t has a trend given by $C\Phi t$, but the cointegration relation, $\beta' x_t$ has no trend because $\beta' C\Phi = 0$.

Interpretation of the *I*(1) Model

In this section, model $H(r)$ defined by [5] is discussed. The parameters in $H(r)$ are

$$(\alpha, \beta, \Gamma_1, \ldots, \Gamma_{k-1}, \Upsilon, \Phi, \Omega)$$

All parameters vary freely and α and β are $p \times r$ matrices. The normalization and identification of α and β are discussed, and some examples of hypotheses on α and β are given.

The Relation between the Models *H*(*r*)

The models $H(r)$ are nested

$$H(0) \subset \ldots \subset H(r) \subset \ldots \subset H(p)$$

Here $H(p)$ is the unrestricted vector autoregressive model, so that α and β are unrestricted $p \times p$ matrices. The model $H(0)$ corresponds to the restriction, $\alpha = \beta = 0$, which is the vector autoregressive model for the process in

differences. Note that in order to have nested models, we allow in $H(r)$ for all processes with rank of α and β less than or equal to r.

The formulation allows us to derive likelihood ratio tests for the hypothesis, $H(r)$ in the unrestricted model, $H(p)$. These tests can be applied to check if one's prior knowledge of the number of cointegration relations is consistent with the data, or alternatively to construct an estimator of the cointegration rank.

Note that when the cointegration rank is r, the number of common trends is $p-r$. Thus, if one can interpret the presence of r cointegration relations, one should also interpret the presence of $p-$ r independent stochastic trends or $p-r$ driving forces in the data.

Normalization of Parameters

The parameters α and β in [5] are not uniquely identified, because given any choice of α and β and any nonsingular $r \times r$ matrix ξ, the choice $\alpha\xi$ and $\beta\xi'^{-1}$ gives the same matrix $\alpha\xi(\beta\xi'^{-1})' = \alpha\xi\xi^{-1}\beta' = \alpha\beta'$.

If $x_t = (x_{1t}', x_{2t}')'$ where x_{1t} is $r \times 1$ and x_{2t} is $(p-r) \times 1$, and $\beta = (\beta_1', \beta_2')'$, with β_1, $r \times r$, and $|\beta_1| \neq 0$, we can solve the cointegration relations as

$$x_{1t} = \gamma' x_{2t} + u_t$$

where u_t is stationary and $\gamma' = -(\beta_1')^{-1}\beta_2'$. This represents cointegration as a regression equation, see Section Regression Formulation. A normalization of this type is sometimes convenient for estimation and calculation of 'standard errors' of the estimator, see Section Asymptotic Distribution of Estimators, but many hypotheses are invariant with respect to a normalization of β, and thus, in a discussion of a test of such a hypothesis, β does not require normalization.

Similarly $\alpha_\perp$ and $\beta_\perp$ are not uniquely defined. From the Granger Representation Theorem we see that the $p-r$ common trends are the nonstationary random walks in $C\sum_{i=1}^t \varepsilon_i$, that is, can be chosen as $\alpha_\perp' \sum_{i=1}^t \varepsilon_i$. For any full rank $(p-r) \times (p-r)$ matrix η, the processes, $\eta\alpha_\perp' \sum_{i=1}^t \varepsilon_i$ could also be used as common trends because

$$C = \beta_\perp(\alpha_\perp' \Gamma \beta_\perp)^{-1}\alpha_\perp' = \beta_\perp(\eta\alpha_\perp' \Gamma \beta_\perp)^{-1}\eta\alpha_\perp'$$

Thus identifying restrictions on the coefficients in $\alpha_\perp$ are needed to find their estimates and standard errors, and a similar result holds for $\beta_\perp$.

In the cointegration model there are therefore four separate identification problems: one for the cointegration relations, one for the common trends, one for $\beta_\perp$, and finally one for the short-run dynamics, if the model has simultaneous effects.

Hypotheses on Long-Run Coefficients

One purpose of modeling economic data is to test hypotheses on the coefficients, thereby investigating whether the data support an economic hypothesis or reject it. As an example consider the series $x_t = (e_t, p_t, p_t^*)'$, where p_t and p_t^* are the log price indices in two countries and e_t the exchange rate. The hypothesis of the law of one price, *PPP*, is that $e_t = p_t - p_t^*$. We formulate that as the hypothesis that (1, −1, 1) is a cointegration vector so that $e_t - p_t + p_t^*$ becomes stationary. Similarly, the hypothesis of price homogeneity is formulated as the restriction

$$R'\beta = (0,1,1)\beta = 0$$
$$\beta = \begin{pmatrix} 1 & 0 \\ 0 & 1 \\ 0 & -1 \end{pmatrix}\begin{pmatrix} \varphi_1 \\ \varphi_2 \end{pmatrix} = H\varphi$$

where $H = R_\perp$. A general formulation of restrictions on each of r cointegration vectors, including a normalization, is

$$\beta = (h_1 + H_1\varphi_1, \ldots, h_r + H_r\varphi_r). \qquad [9]$$

Here h_i is $p \times 1$ and orthogonal to H_i, which is $p \times (s_i - 1)$ of rank $s_i - 1$, so that $p - s_i$ restrictions are imposed on the vector, β_i. Let the restrictions be $R_i = (h_i, H_i)_\perp$ then β_i satisfies $R_i'\beta_i = 0$, and the normalization $(h_i'h_i)^{-1}h_i'\beta_i = 1$. The usual rank condition for identification is that β_i is identified by $R_i'\beta_i = 0$, if

$$\operatorname{rank}\left(R_i'(\beta_1, \ldots, \beta_r)\right) = r - 1$$

Hypotheses on Adjustment Coefficients

The coefficients in α measure how the process adjusts to disequilibrium errors. The hypothesis of weak exogeneity is the hypothesis that some rows of α are zero; see Engle et al. (1983). We decompose the process x_t as $x_t = (x_{1t}', x_{2t}')'$ and the matrices are decomposed similarly so that the model equations (without deterministic terms and $k = 2$) become

$$\Delta x_{1t} = \alpha_1\beta' x_{t-1} + \Gamma_{11}\Delta x_{t-1} + \varepsilon_{1t}$$
$$\Delta x_{2t} = \alpha_2\beta' x_{t-1} + \Gamma_{21}\Delta x_{t-1} + \varepsilon_{2t}$$

The conditional model for Δx_{1t} given Δx_{2t} and the past is

$$\Delta x_{1t} = \omega\Delta x_{2t} + \alpha_1\beta' x_{t-1} + (\Gamma_{11} - \omega\Gamma_{21})\Delta x_{t-1} + \varepsilon_{1t} - \omega\varepsilon_{2t} \qquad [10]$$

where $\omega = \Omega_{12}\Omega_{22}^{-1}$. If $\alpha_2 = 0$, there is no levels feedback from $\beta' x_{t-1}$ to Δx_{2t}, and if the errors are Gaussian, x_{2t} is called weakly exogenous for α_1 and β. In this case the likelihood is a product of two factors depending on $(\Gamma_{21}, \Omega_{22})$ and $(\alpha_1, \beta, \Gamma_{11}, \omega, \Omega_{11.2})$, respectively. Because the parameters are unrestricted (variation independent), likelihood inference on β and α_1 can be conducted in the conditional model alone.

If the hypothesis of weak exogeneity is not satisfied, inference of the conditional model is complicated because limit distributions contain nuisance parameters, and asymptotic inference is not Gaussian.

If x_{2t} is weakly exogenous, $\alpha_\perp$ contains the columns of $(0, I_{p-r})'$, so that $\sum_{i=1}^t \varepsilon_{2i}$ are common trends. Thus the errors in the equations for Δx_{2t} cumulate in the system and give rise to nonstationarity.

Likelihood Analysis

This section contains first some comments on what aspects of the data are important for checking for model misspecification, and then describes the calculation of reduced rank regression, introduced by Anderson (1951). Then reduced rank regression

and modifications thereof are applied to estimate the parameters of the $I(1)$ model [5] and various submodels defined by restrictions on β, see Johansen and Juselius (1990).

Checking for Specification

In order to apply Gaussian maximum likelihood methods, the assumptions behind the model have to be checked carefully, so that one is convinced that the statistical model contains the density that generated the data. If this is not the case, the asymptotic results available from the Gaussian analysis need not hold. Methods for checking vector autoregressive models include choice of lag length, test for normality of residuals, tests for autocorrelation, and test for heteroscedasticity in errors. Asymptotic results for estimators and tests derived from the Gaussian likelihood turn out to be robust to some types of deviations from the above assumptions. Thus the limit results hold for independent identically distributed (iid) errors with finite variance, and not just for Gaussian errors, but autocorrelated errors violate the asymptotic results, so autocorrelation has to be checked carefully.

Finally and perhaps most importantly, the assumption of constant parameters is crucial. In practice it is important to model outliers by suitable dummies, but it is also important to model breaks in the dynamics, breaks in the cointegration properties, breaks in the stationarity properties, etc. The papers by Seo (1998) and Hansen and Johansen (1999) contain some results on recursive tests in the cointegration model, and Doornik and Hendry (2013) contains a description of a general algorithm (*Autometrics*) for finding a model that describes the data.

Reduced Rank Regression

Let u_t, w_t, and z_t be three multivariate time series of dimensions p_u, p_w, and p_z respectively. The algorithm of reduced rank regression, see Anderson (1951), can be described in the regression model

$$u_t = \alpha\beta' w_t + \Xi z_t + \varepsilon_t$$

where ε_t are iid $(0,\Omega)$. The product moments are

$$S_{uw} = T^{-1}\sum_{t=1}^{T} u_t w_t'$$

and the residuals, which we get by regressing u_t on w_t, are

$$(u_t|w_t) = u_t - S_{uw}S_{ww}^{-1}w_t$$

so that the conditional product moments are

$$S_{uw.z} = S_{uw} - S_{uz}S_{zz}^{-1}S_{zw} = T^{-1}\sum_{t=1}^{T}(u_t|z_t)(w_t|z_t)'$$

$$S_{uu.w,z} = T^{-1}\sum_{t=1}^{T}(u_t|w_t,z_t)(u_t|w_t,z_t)' = S_{uu.w} - S_{uz.w}S_{zz.w}^{-1}S_{zu.w}$$

For fixed β the regression estimates are

$$\widehat{\alpha}(\beta) = S_{uw.z}\beta(\beta' S_{ww.z}\beta)^{-1}$$
$$\widehat{\Omega}(\beta) = S_{uu.z} - S_{uw.z}\beta(\beta' S_{ww.z}\beta)^{-1}\beta' S_{wu.z}$$

so that

$$|\widehat{\Omega}(\beta)| = |S_{uu.w}|\frac{|\beta' S_{ww.uz}\beta|}{|\beta' S_{ww.z}\beta|}$$

Minimizing over β gives the reduced rank estimators. This minimization problem is solved as follows. First we solve the eigenvalue problem

$$\left|\lambda S_{ww.z} - S_{wu.z}S_{uu.z}^{-1}S_{uw.z}\right| = 0$$

The eigenvalues are ordered $\widehat{\lambda}_1 \geq \ldots \geq \widehat{\lambda}_{p_w}$ with corresponding eigenvectors $\widehat{v}_1, \ldots \widehat{v}_{p_w}$. The reduced rank estimate of β is

$$\widehat{\beta} = (\widehat{v}_1, \ldots, \widehat{v}_r) \qquad [11]$$

and the other estimators are found by regression of u_t on $\widehat{\beta}' x_{t-1}$ and z_t. Finally we find

$$|\widehat{\Omega}| = |S_{uu.z}|\prod_{i=1}^{r}\left(1 - \widehat{\lambda}_i\right)$$

The eigenvectors are orthogonal with respect to $S_{ww.z}$, that is, $\widehat{v}_i' S_{ww.z}\widehat{v}_j = 0$ for $i \neq j$, and they are normalized by $\widehat{v}_i' S_{ww.z}\widehat{v}_i = 1$. The calculations described here are called a reduced rank regression and are denoted by $RRR(u_t, w_t \mid z_t)$.

Likelihood Analysis

It is assumed for the likelihood analysis that ε_t is iid $N_p(0, \Omega)$, but for asymptotic results the Gaussian assumption is not needed. The Gaussian likelihood function shows that the maximum likelihood estimator can be found by the reduced rank regression of Δx_t on $(x'_{t-1}, D'_t)'$ correcting for $\mathbb{X}_t = (\Delta x'_{t-1}, \ldots, \Delta x'_{t-k+1}, d'_t)'$

$$RRR\left(\Delta x_t, \begin{pmatrix} x_{t-1} \\ D_t \end{pmatrix} | \mathbb{X}_t\right)$$

The estimates are given by [11], and the maximized likelihood is, apart from a constant, given by

$$L_{\max}^{-2/T} = |\widehat{\Omega}| = |S_{00}|\prod_{i=1}^{r}\left(1 - \widehat{\lambda}_i\right) \qquad [12]$$

where $S_{00} = T^{-1}\sum_{t=1}^{T}(\Delta X_t|\mathbb{X}_t)(\Delta X_t|\mathbb{X}_t)'$.

Note that all the models, $H(r)$, $r = 0, \ldots, p$, have been solved by the same eigenvalue calculation. The maximized likelihood is given for each r by [12] and by dividing the maximized likelihood function for r with the corresponding expression for $r = p$, the likelihood ratio test for cointegration rank is obtained:

$$-2\log LR(H(r)|H(p)) = -T\sum_{i=r+1}^{p}\log\left(1 - \widehat{\lambda}_i\right)$$

The asymptotic distribution of this test statistic and the estimators are discussed in section Asymptotic Analysis.

The model obtained under the hypothesis, $\beta = H\varphi$ is analyzed by

$$RRR\left(\Delta x_t, \begin{pmatrix} H'X_{t-1} \\ D_t \end{pmatrix} | \mathbb{X}_t\right)$$

and a number of hypotheses of this type for β and α can be solved in the same way, but the more general hypothesis

$$\beta = (h_1 + H_1\varphi_1, \ldots, h_r + H_r\varphi_r)$$

see [9], cannot be solved by reduced rank regression.

Asymptotic Analysis

A discussion of the most important aspects of the asymptotic analysis of the cointegration model is given. This includes the result that the rank test requires a family of Dickey–Fuller type distributions, depending on the specification of the deterministic terms of the model. The asymptotic distribution of $\widehat{\beta}$ is mixed Gaussian and that of the remaining parameters is Gaussian, so that tests for hypotheses on the parameters are asymptotically distributed as χ^2.

Asymptotic Distribution of the Rank Test

The asymptotic distribution of the rank test is given in case the process has a linear trend.

Theorem 3: Let ε_t be iid $(0, \Omega)$ and assume that $D_t = t$ and $d_t = 1$, in model [5]. Under the assumptions that the cointegration rank is r, the asymptotic distribution of the likelihood ratio test statistic $-2\log LR(H(r)|H(p))$, [13], is

$$tr\left\{\int_0^1 (dB)F'\left(\int_0^1 FF'du\right)^{-1}\int_0^1 F(dB)'\right\} \qquad [13]$$

where F is defined by

$$F(u) = \left(\begin{array}{c|c} B(u) & \\ u & 1 \end{array}\right)$$

and $B(u)$ is the $p - r$ dimensional standard Brownian motion.

The limit distribution is tabulated by simulation. Note that it does not depend on the parameters $(\Gamma_1,\ldots,\Gamma_{k-1},\Upsilon,\Phi,\Omega)$, but only on $p - r$, the number of common trends, and the presence of the linear trend. For finite samples, however, the dependence on the parameters can be quite pronounced. A small sample correction for the test has been given in Johansen (2002), and the bootstrap has been investigated by Rahbek et al. (2012).

In the model without deterministics, the same result holds, but with $F(u) = B(u)$. A special case of this, for $p = 1$, is the Dickey–Fuller test and the asymptotic distributions given in Theorem 3 are called the Dickey–Fuller distributions with $p - r$ degrees of freedom; see Dickey and Fuller (1981).

Asymptotic Distribution of Estimators

The main result here is that the estimator of β, suitably normalized, converges to a mixed Gaussian distribution; see Johansen (1988). This result implies that likelihood ratio tests on β are asymptotically χ^2 distributed. Furthermore the estimators of the adjustment parameters α and the short-run parameters, Γ_i are asymptotically Gaussian and asymptotically independent of the estimator for β.

To illustrate how to conduct inference on a cointegrating coefficient, and why it becomes asymptotic χ^2 despite the asymptotic mixed Gaussian limit of $\widehat{\beta}$, we consider an example.

Example 4: (Mixed Gaussian distribution) Let x_t be a bivariate process with one lag for which $\alpha = (-1, 0)'$ and $\beta = (1, \theta)'$. The equations become

$$\begin{aligned} x_{1t} &= \theta x_{2t-1} + \varepsilon_{1t} \\ \Delta x_{2t} &= \varepsilon_{2t} \end{aligned} \qquad [14]$$

This model as a special case of [5] with $\alpha' = (-1, 0), \beta' = (1, -\theta), p = 2, k = 1$. If we add the assumption that ε_t is Gaussian with mean zero and variance $\Omega = diag(\sigma_1^2, \sigma_2^2)$ the maximum likelihood estimator simplifies to a regression estimator, and becomes

$$\widehat{\theta} = \frac{\sum_{t=1}^T x_{1t}x_{2t-1}}{\sum_{t=1}^T x_{2t-1}^2} = \theta + \frac{\sum_{t=1}^T \varepsilon_{1t}x_{2t-1}}{\sum_{t=1}^T x_{2t-1}^2}$$

The distribution of $\widehat{\theta}$ conditional on the whole process $\{x_{2t}\}_{t=1}^T$ is clearly Gaussian:

$$\widehat{\theta}\big|\{x_{2t}\}\text{is distributed as } N\left(\theta, \sigma_1 \Big/ \sum_{t=1}^T x_{2t-1}^2\right)$$

By integrating out the process x_{2t} we get a distribution which we call mixed Gaussian with mixing parameter $1/\sum_{t=1}^T x_{2t-1}^2$, and hence

$$E\left(\widehat{\theta}\right) = \theta \quad \text{and} \quad Var\left(\widehat{\theta}\right) = \sigma_1^2 E\left(1 \Big/ \sum_{t=1}^T x_{2t-1}^2\right)$$

When constructing a test for $\theta = \theta_0$ we do not use

$$\left(\widehat{\theta} - \theta\right) \Big/ Var\left(\widehat{\theta}\right)^{1/2}$$

but instead expand the likelihood function and find the Wald test, which is based on the observed information:

$$\widehat{\sigma}_1^{-1}\left(\sum_{t=1}^T x_{2t-1}^2\right)^{1/2}\left(\widehat{\theta} - \theta\right)$$

This statistic is asymptotically distributed as $N(0, 1)$: Thus we normalize by the observed information, $\sum_{t=1}^T x_{2t-1}^2/\sigma_1^2$, not the expected information often used when analyzing stationary processes.

Figure 4 shows a scatter diagram of 1000 simulations of $(\widehat{\theta}, \sum_{t=1}^T x_{2t-1}^2/\sigma_1^2)$. That is, the estimator and the information about the parameter. We note that when the information is large, the variation of $\widehat{\theta}$ is small, and when the information is small, the variation of $\widehat{\theta}$ is much larger. Thus the variation of $\widehat{\theta}$ should be measured by its conditional variance, which is the reciprocal information in the data. This has the further advantage that if we only consider those estimates with a given information we see that $\widehat{\theta}$ is approximately Gaussian.

The main result is that tests on β are asymptotically distributed as χ^2, and we formulate that as.

Theorem 4: Let εt be iid $(0, \Omega)$. The asymptotic distribution of the likelihood ratio test statistic for the restrictions [9] in model [5] is distributed as χ^2 with degrees of freedom given by $\sum_{i=1}^r (p - r - s_i + 1)$. A small sample correction for some tests on β has been developed in Johansen (2000).

Further Topics in Cointegration

The basic model for $I(1)$ processes has been extended to other types of nonstationarity. In particular models for seasonal roots, Ahn and Reinsel (1994) and Johansen and Schaumburg (1998), explosive processes, Nielsen (2010), $I(2)$ processes, Johansen (1997), fractional processes, Johansen and Nielsen (2012), nonlinear processes, Lange and Rahbek (2009), panel data cointegration, Larsson et al. (2001) and Pesaran et al.

Figure 4 A scatter plot of $\widehat{\theta} = \sum_{i=1}^{T} x_{1t} x_{2t-1} / \sum_{i=1}^{T} x_{2,t-1}^2$ and the information. $\sum_{i=1}^{T} x_{2,t-1}^2 / \sigma_1^2$ for model [14]. The number of observations is $T = 100$, and the number of simulations is 1000.

(2004), and finally applications to rational expectation models, Johansen and Swensen (2011).

Concluding Remarks

In summary one can say, that what has been developed for the CVAR model is a set of useful tools for the analysis of many types of economic time series. The theory is now part of many textbooks, and software for the analysis of data has been implemented in several packages, e.g., in CATS, in RATS, Givewin, Eviews, Microfit, Shazam, R, Gauss, GRETL, etc.

We have given a brief tour in the cointegration landscape showing some of the major sights without indicating, except by examples, how the formal analysis is conducted. We concluded with a list of extensions of the basic model, which shows that the ideas behind the CVAR extend to a large number of other models.

Time Series: Cycles

Mark W Watson, Princeton University, Princeton, NJ, USA

Abstract

This article discusses cyclical (or periodic) properties of stochastic processes. The spectrum (or spectral density function) is introduced as a method for characterizing the approximate periodic behavior of realizations from stochastic processes. The spectral representation is introduced as a way to decompose a stochastic process into its periodic components. Moving average filters change the cyclical properties of time series, and formulae characterizing these changes are developed. Specific moving average filters are discussed, and general formulae for extracting components associated with specific frequencies (bandpass filters) are presented. Spectral properties of ARMA process are derived. Methods for estimating spectra are outlined.

Time series data in economics and other fields of social science often exhibit cyclical behavior. For example, aggregate retail sales are high in November and December and follow a seasonal cycle; voter registrations are high before each presidential election and follow an election cycle; and aggregate macro-economic activity falls into recession every six to eight years and follows a business cycle. In spite of this cyclicality, these series are not perfectly predictable, and the cycles are not strictly periodic. That is, each cycle is unique. Quite generally, it is useful to think of time series as realizations of stochastic processes, and this raises the question of how to represent cyclicality in stochastic processes. The major descriptive tool for this is the 'spectral density function' (or 'spectrum'), which is the subject of this article.

Cycles in a Typical Time Series

Figure 1 shows a time series plot of new housing authorizations ('building permits') issued by communities in the USA, monthly, from 1960 through 1999. This plot has characteristics that are typical of many economic time series. First, the plot shows a clear seasonal pattern: permits are low in the late fall and early winter, and rise markedly in the spring and summer. This seasonal pattern is persistent throughout the sample period, but does not repeat itself exactly year-after-year. In addition to a seasonal pattern, there is a slow moving change in the level of the series associated with the business cycle. For example, local minima of the series are evident in 1967, the mid-1970s, the early 1980s, and in 1990, which correspond to periods of macroeconomic slowdown or recession in the US economy.

How can the cyclical variability in the series be represented? One approach is to use a periodic function like a sine or cosine function. But this is inadequate in at least two ways. First, a deterministic periodic function doesn't capture the randomness in the series. Second, since several different periodicities (seasonal, business cycle) are evident in the plot, several periodic functions will be required. The next section presents a representation of a stochastic process that has these ingredients.

Figure 1 Building permits in the USA.

Representing Cyclical Behavior in Time Series: The Spectrum

Spectral Representation of a Covariance Stationary Process

Consider a sequence of scalar random variables $\{Y_t\}$ where $t = 0, \pm 1, \pm 2, \ldots$, and $E(Y_t) = \mu$, $Cov(Y_t Y_{t-k}) = \lambda_k$. That is, assume that Y_t is observed at regular intervals, like a week, a month, a year, etc. Assume that the first and second moments of the process do not depend on time, that is μ and λ_k are time invariant. To simplify notation, assume that $\mu = 0$.

To motivate the spectral representation of Y_t, it is useful to begin with a very special and simple stochastic process:

$$Y_t = \alpha \cos(\omega t) + \delta \sin(\omega t) \qquad [1]$$

where α and δ are random variables with $E(\alpha) = E(\delta) = 0$; $E(\alpha\delta) = 0$; and $E(\alpha^2) = E(\delta^2) = \sigma^2$. While simple, this process has three attractive characteristics. First, it is periodic: since $\cos(a + 2\pi) = \cos(a)$ and $\sin(a + 2\pi) = \sin(a)$, then $Y_{t+j2\pi/\omega} = Y_t$ for $|j| = 1, 2, \ldots$. So Y_t repeats itself with a period of $2\pi/\omega$. Second, the random components α and δ give Y a random amplitude (value of at its peak) and a random phase (value at $t = 0$). Thus, two realizations of Y will have different amplitudes and different timing of their peaks and troughs. Finally, the process is covariance stationary with $E(Y_t) = 0$ and $\lambda_k = \sigma^2 \cos(\omega k)$.

Adding together several components like eqn [1] produces a more interesting stochastic process:

$$Y_t = \sum_{j=1}^{n} \left[\alpha_j \cos(\omega_j t) + \delta_j \sin(\omega_j t)\right] \qquad [2]$$

with $E(\alpha_j) = E(\delta_j) = 0$, for all j; $E(\alpha_j \delta_k) = 0$, for all j, k; $E(\alpha_j, \alpha_k) = E(\delta_j \delta_k) = 0$, for $j \neq k$; and $E(\alpha_j^2) = E(\delta_j^2) = \sigma_j^2$. For this process, Y_t is the sum of n different uncorrelated components, each corresponding to a different frequency, and each with its own variance. (The variance of $\alpha_j \cos(\omega_j t) + \delta_j \sin(\omega_j t)$ is σ_j^2.) A calculation shows $E(Y_t) = 0$, $\lambda_k = \sum_{j=1}^{n} \sigma_j^2 \cos(\omega_j k)$, and the variance of Y_t is given by $var(Y_t) = \sum_{j=1}^{n} \sigma_j^2$.

So far, this has all been special. That is, two very special processes have been constructed. However, a fundamental result (Cramér, 1942; Kolmorgorov, 1940) shows that a generalization of this decomposition can be used to represent any covariance stationary process. The result, known as the 'Spectral Representation Theorem,' says that if Y_t is covariance stationary, then it can be represented as

$$Y_t = \int_0^{\pi} \cos(\omega t) d\alpha(\omega) + \int_0^{\pi} \sin(\omega t)\, d\delta(\omega)$$

where $d\alpha(\omega)$ and $d\delta(\omega)$ are zero mean random variables that are mutually uncorrelated, uncorrelated across frequency, and have variances that depend on frequency. Like the special example shown in eqn [2], this general representation decomposes Y_t into a set of strictly periodic components – each uncorrelated with the others, and each with its own variance. For example, processes with important seasonal components will have large values of the components corresponding to the seasonal frequency, processes for series with strong 'business cycle' components will have large variances at business cycle frequencies, etc.

Sometimes the spectral representation is written using complex numbers as:

$$Y_t = \int_{-\pi}^{\pi} e^{i\omega t} d\gamma(\omega) \qquad [3]$$

where $d\gamma(\omega) = (1/\sqrt{2})\,[d\alpha(\omega) - i d\delta(\omega)]$ for $\omega \geq 0$ and $d\gamma(\omega) = d\gamma(-\omega)$ for $\omega < 0$. This representation simplifies notation for some calculations.

The spectral representation eqn [3] is a generalization of eqn [2] where the 'increments' $d\gamma(\omega)$ have orthogonality properties like those of α_j and δ_j. The variance of each component is frequency specific (like σ_j^2), and is summarized by a density function $S(\omega)$. Specifically, the variance of $d\gamma(\omega)$ is $E(d\gamma(\omega)\, d\gamma(\omega)) = S(\omega) d\omega$. (The use of a density function to summarize the variance of $d\gamma(\omega)$ is not completely general and rules out processes with deterministic (or perfectly predictable) components. The references listed in the last section provide this more general result.)

You may wonder why the spectral representation doesn't use frequencies larger than π. The answer is that these are not needed to describe a process measured at discrete intervals. This discreteness means that periodic components associated with frequencies larger than π will look just like components associated with frequencies less than π. For example, a component with frequency 2π will have period of 1 and, because the series is measured only once every period, this component will appear to be constant – it will look just like (be 'aliased' with) a component that has a frequency of $\omega = 0$.

Relationship between the Spectral Density and the Autocovariances

There is a one-to-one relationship between the spectral density function and the autocovariances of the process. The autocovariances follow directly from the spectral representation:

$$\begin{aligned} \lambda_k &= E(Y_t Y_{t-k}) = E(Y_t \overline{Y}_{t-k}) \\ &= E\left[\int e^{i\omega t} d\gamma(\omega) \int e^{-i\omega(t-k)} \overline{d\gamma(\omega)}\right] \\ &= \int e^{i\omega k} S(\omega) d\omega. \end{aligned} \qquad [4]$$

The spectrum can be determining by inverting this relation:

$$S(\omega) = (2\pi)^{-1} \sum_{j=-\infty}^{\infty} \lambda_j e^{-i\omega j} \qquad [5]$$

(To verify that eqn [5] is the inverse of eqn [4], use.

$$\int_{-\pi}^{\pi} e^{iwk} dw = \begin{Bmatrix} 2\pi & \text{for} & k = 0 \\ 0 & \text{for} & k \neq 0 \end{Bmatrix} \qquad [6]$$

so that $(2\pi)^{-1}\{\int_{-\pi}^{\pi} \sum_{j=-\infty}^{\infty} \lambda_j e^{-i\omega(j-k)} d\omega\} = \lambda_k$.

A simpler formula for the spectrum is.

$$S(\omega) = (2\pi)^{-1} \left[\lambda_0 + 2 \sum_{j=1}^{\infty} \lambda_j \cos(j\omega)\right]. \qquad [7]$$

which follows from eqn [5], since $\lambda_j = Cov(Y_t Y_{t-j}) = Cov(Y_{t+j} Y_t) = \lambda_{-j}$.

A Summary of the Properties of the Spectrum

Summarizing the results presented in Section Relationship between the Spectral Density and the Autocovariances, the spectrum (or spectral density function) has 4 important properties.

1. $S(\omega)d\omega$ can be interpreted as the variance of the cyclical component of Y corresponding to the frequency ω. The period of this component is $2\pi/\omega$.
2. $S(\omega) \geq 0$. This follows, because $S(\omega)$ is a variance function.
3. $S(\omega) = S(-\omega)$. This follows from the definition of $\gamma(\omega)$ in the spectral representation eqn [3], or from eqn [7], since $\cos(a) = \cos(-a)$. Because of this symmetry, plots of the spectrum are presented $0 \leq \omega \leq \pi$.
4. $Var(Y) = \int_{-\pi}^{\pi} S(\omega)\mathrm{d}\omega$.

The Spectrum of Building Permits

The time series plot of building permits (**Figure 1**) shows that most of the variability in the series comes from two sources: seasonal variation over the year and business-cycle variability. This is evident in the estimated spectrum for the series, shown in **Figure 2**. Most of the mass in the spectrum is concentrated around the seven peaks evident in the plot. (These peaks are sufficiently large that spectrum is plotted on a log scale.) The first peak occurs at frequency $\omega = 0.07$ corresponding to a period of 90 months. This represents the business cycle variability in the series. The other peaks occur at frequencies $2\pi/12$, $4\pi/12$, $6\pi/12$, $8\pi/12$, and π. These are peaks for the seasonal frequencies: the first corresponds to a period of 12 months, and the others are the seasonal 'harmonics' 6, 4, 3, and 2 months.

Spectral Properties of Moving Average Filters

Some General Results

Often, one time series (Y) is converted into another time series (X) through a moving average function such as:

$$X_t = \sum_{j=-r}^{s} c_j Y_{t-j}$$

For example, X_t might be the first difference of Y_t, i.e., $X_t = Y_t - Y_{t-1}$, or an annual moving average $X_t = \frac{1}{12}\sum_{j=0}^{11} Y_{t-j}$, or one of the more complicated moving averages that approximate official seasonal adjustment procedures (*see* Time Series: Seasonal Adjustment).

Let the 'lag' operator L shift time series back by one period (so that $LY_t = Y_{t-1}$, $L^2Y_t = L(LY_t) = Y_{t-2}$, $L^{-1}Y_t = Y_{t+1}$, etc.), then this moving average can be represented as:

$$X_t = c(L)Y_t$$

where,

$$c(L) = c_{-r}L^{-r} + \cdots + c_{-1}L^{-1} + c_0L^0 + c_1L + \cdots + c_sL^s$$

The operator $c(L)$ is sometimes called a 'linear filter.'

How does $c(L)$ change the spectral properties of Y? If the spectral representation of Y_t is written as:

$$Y_t = \int_{-\pi}^{\pi} \mathrm{e}^{i\omega t}\mathrm{d}\gamma(\omega)$$

then X_t can be written as,

$$\begin{aligned} X_t &= \sum_{j=-r}^{s} c_j Y_{t-j} = \sum_{j=-r}^{s} c_j \int_{-\pi}^{\pi} \mathrm{e}^{i\omega(t-j)}\mathrm{d}\gamma(\omega) \\ &= \int_{-\pi}^{\pi} \mathrm{e}^{i\omega t}\left(\sum_{j=-r}^{s} c_j \mathrm{e}^{-i\omega j}\right)\mathrm{d}\gamma(\omega) \\ &= \int_{-\pi}^{\pi} \mathrm{e}^{i\omega t} c(\mathrm{e}^{i\omega})\mathrm{d}\gamma(\omega) \\ &= \int_{-\pi}^{\pi} \mathrm{e}^{i\omega\left(t - \frac{p(\omega)}{\omega}\right)} g(\omega)\mathrm{d}\gamma(\omega) \end{aligned} \qquad [8]$$

where the last line uses the polar form of $c(\mathrm{e}^{-i\omega})$: $c(\mathrm{e}^{-i\omega}) = g(\omega)\mathrm{e}^{-ip(\omega)}$ where

$$g(\omega) = \left|c(\mathrm{e}^{i\omega})\right| \qquad [9]$$

Figure 2 Spectrum of building permits.

and

$$\rho(\omega) = \tan^{-1}\left[\frac{-\mathrm{Im}\left[c\left(e^{-i\omega}\right)\right]}{\mathrm{Re}\left[c\left(e^{-i\omega}\right)\right]}\right] \qquad [10]$$

This representation for X_t shows that the filter $c(L)$ 'amplifies' each component of Y_t by the factor $g(\omega)$ and shifts it back in time by $\rho(\omega)/\omega$ time units.

The function $g(\omega)$ is called the filter *gain* (or sometimes the 'amplitude gain.' The function $\rho(\omega)$ is called the filter 'phase' and $g(\omega)^2 = [c(e^{-i\omega})c(e^{-i\omega})]$ is called the 'power transfer function' of the filter.

Three Examples

Example One: Lag Filter

Suppose that $c(L) = L^2$. Then $c(e^{-i\omega}) = e^{-2i\omega}$.

$$g(\omega) = \left|c\left(e^{i\omega}\right)\right| = 1$$

and

$$\rho(\omega) = \tan^{-1}\left[\frac{\sin 2\omega}{\cos 2\omega}\right] = 2\omega$$

Thus, this filter does not alter the amplitude of any of the components, $g(\omega) = 1$, but shifts each component back in time by $\rho(\omega)/\omega = 2$ time periods.

Example Two: First Difference Filter

Suppose that $c(L) = (1 - L)$ so that X_t is the first difference of Y_t. Then $c(e^{-i\omega}) = 1 - e^{-i\omega}$,

$$g(\omega) = \left(-e^{-i\omega} + 2 - e^{i\omega}\right)^{\frac{1}{2}} = \sqrt{2(1-\cos(\omega))}$$

and

$$\rho(\omega) = \tan^{-1}\left[\frac{\sin(\omega)}{1-\cos(\omega)}\right]$$

Thus, both the gain and phase are frequency specific. For example, $g(0) = 0$ so that the first difference filter eliminates the lowest frequency component of the series (the level of the series is 'differenced out'), and $g(\pi) = \sqrt{2}$ so that the high frequency components are amplified (X_t is 'choppier' than Y_t).

Example Three: Census X-12 Seasonal Adjustment Filter

The official monthly seasonal adjustment procedure in the USA and several other countries (Census X-12) can be linear filter $c(L) = \sum_{j=-84}^{84} c_{|j|}L^j$ where the coefficients c_i are given in Wallis (1974). Since the filter is symmetric, $c_j = c_{-j}$, $c(e^{i\omega})$ is real and so $\rho(\omega) = 0$. The function $g(\omega)$ is plotted in Figure 3. The gain is nearly unity except near the seasonal frequencies, and so the filter can be interpreted as producing a new series that leaves the non-seasonal components unaltered, but eliminates the seasonal components. For a detailed discussion of seasonal adjustment procedures *see* Time Series: Seasonal Adjustment.

Band-Pass Filters

The seasonal adjustment filter has the desirable properties of (essentially) zeroing out certain frequency components (the 'seasonal') and leaving the other components (the non-seasonals) unaltered. Filters with this characteristic are called 'band-pass filters,' since they 'pass' components associated with certain frequencies.

Band-pass filters for prespecified frequencies are easy to construct. For example, suppose that you want a filter with no phase shift that passes components between $0 \le \omega \le \underline{\omega}$. That is, you want to construct a filter, say $c(L)$ with gain $|g(\omega)| = 1$ for $0 \le \omega \le \underline{\omega}$ and $|g(\omega)| = 0$ for $\underline{\omega} \le \omega \le \pi$. (Assume that the corresponding negative frequencies are also passed.) Choosing a symmetric filter, $c_j = c_{-j}$, will make the phase 0 for all ω. In this case, $c(e^{i\omega})$ is a real number, and so the gain is given by:

$$g(\omega) = \sum_{j=-\infty}^{\infty} c_{|j|}e^{-i\omega j}$$

Now, using eqn [6], it is straightforward to verify the identity.

$$c_j = (2\pi)^{-1}\int_{-\pi}^{\pi} e^{-i\omega j}\sum_{j=-\infty}^{\infty} c_j e^{-i\omega j}\mathrm{d}\omega$$
$$= (2\pi)^{-1}\int_{-\pi}^{\pi} e^{i\omega j}\, c\left(e^{i\omega}\right)\mathrm{d}\omega$$

Figure 3 Gain of linear approximation to monthly × 12 seasonal adjustment filter.

Replacing $c(e^{i\omega}) = g(\omega)$ with the target value of the gain for the band-pass filter and carrying out the integration yield.

$$c_j = (2\pi)^{-1}\frac{1}{ij}e^{i\omega j}\Big|_{-\underline{\omega}}^{\underline{\omega}} = \left\{\begin{array}{ll} \frac{1}{j\pi}\sin\left(\underline{\omega}j\right) & \text{for} \quad j \neq 0 \\ \underline{\omega}/\pi & \text{for} \quad j = 0 \end{array}\right\}$$

The resulting filter $c(L)$ passes all components with frequencies between $0 \leq \omega \leq \underline{\omega}$. This means that the filter $1\text{–}c(L)$ passes everything except these frequencies. The filter $c(L)$ is called a low-pass filter (it passes low frequencies), and $1\text{–}c(L)$ is called a high-pass filter (it passes the high frequencies). Combinations of high- and low-pass filters can be used to construct band-pass filters for any set of frequencies. For example, a filter that passes components with frequencies between ω_1 to ω_2 (with $\omega_1 \geq \omega_2$) can be constructed as the difference of the low-pass filter for ω_2 and the low-pass filter for ω_1.

One practical problem with exact band-pass filters is that the coefficients c_j die out very slowly (at the rate $1/j$). This introduces important 'endpoint' problems when applying these filters to finite realizations of data, say $\{Y_t\}_{t=1}^{T}$. One approach is simply to truncate the filter at some point, for example to use $c_k(L) = \sum_{j=-k}^{k} c_j L^j$ and apply this filter to $\{Y_t\}_{t=k+1}^{T-k}$. An alternative procedure is to construct a minimum mean square error estimate of the infeasible band-pass values:

$$X_t = c(L)Y_t = \sum_{i=-\infty}^{\infty} c_i Y_{t-i},$$

as

$$E\left(X_t \middle| \{Y_j\}_{j=1}^{T}\right) = \sum_{i=-\infty}^{\infty} c_i E\left(Y_{t-i} \middle| \{Y_j\}_{j=1}^{T}\right)$$

This can be accomplished by using backcasts and forecasts for the missing pre-sample and post-samples values of Y_t. The relative merits of these two approaches for band-pass filters is discussed in Baxter and King (1999), Geweke (1978), and Dagum (1980) discuss this problem in the context of seasonal adjustment.

Spectra of Commonly Used Stochastic Processes

Suppose that Y has spectrum $S_Y(\omega)$ and $X_t = c(L)\,Y_t$. What is the spectrum of X? As was shown in eqn [8], the frequency components of X are the frequency components of Y scaled by the factor $g(\omega)e^{i\rho(\omega)}$, where $g(\omega)$ is the gain and $\rho(\omega)$ is the phase of $c(L)$. This means that spectra of X and Y are related by:

$$S_X(\omega) = g(\omega)^2 S_Y(\omega) = \left|c\left(e^{-i\omega}\right)\right|^2 S_Y(\omega)$$

which follows from $|e^{i\rho(\omega)}| = 1$ and the definition of $g(\omega)$.

Now, suppose that ε_t is a 'white noise' process, defined by the properties $E(\varepsilon_t) = 0$, $\lambda_0 = \sigma^2$, and $\lambda_k = 0$ for $k \neq 0$. The spectrum of ε is then easily calculated from eqn [7]:

$$S_\varepsilon(\omega) = (2\pi)^{-1}\sigma^2$$

So, the spectrum of white noise is constant. (Which is why the process is called 'white' noise.) Now suppose that $Y_t = c(L)\varepsilon_t$. Then:

$$S_Y(\omega) = \left|c\left(e^{-i\omega}\right)\right|^2 S_\varepsilon(\omega) = \left|c\left(e^{-i\omega}\right)\right|^2 (2\pi)^{-1}\sigma^2$$

This result can be used to determine the spectrum of any stationary ARMA process (*see* Time Series: ARIMA Methods) for a detailed discussion of these models). If Y_t follows an ARMA process, then it can be represented as:

$$\phi(L)Y_t = \theta(L)\varepsilon_t$$

The autoregressive operator, $\phi(L)$ can be inverted to yield $Y_t = c(L)\varepsilon_t$ with $c(L) = \phi(L)^{-1}\theta(L)$. This means that:

$$S_Y(\omega) = \left|c\left(e^{-i\omega}\right)\right|^2 (2\pi)^{-1}\sigma^2 = \frac{2(\pi)^{-1}\sigma^2\left|\theta\left(e^{-i\omega}\right)\right|^2}{\left|\phi\left(e^{-i\omega}\right)\right|^2} \qquad [11]$$

As an example, consider the AR(1) model:

$$Y_t = \phi Y_{t-1} + \varepsilon_t$$

equivalently written as,

$$(1 - \phi L)Y_t = \varepsilon_t.$$

Applying eqn [11] yields.

$$S_Y(\omega) = \frac{\sigma^2}{2\pi}\frac{1}{\left|1 - \phi e^{-i\omega}\right|^2} = \frac{\sigma^2}{2\pi}\frac{1}{\left(1 + \phi^2 - 2\phi\cos(\omega)\right)}$$

This spectrum is equal to $\sigma^2[2\pi(1 + \phi^2 - 2\phi\cos(\omega))]^{-1}$ at $\omega = 0$. When $0 < \phi < 1$, it falls steadily as ω increases from 0 to π. This means that, relative to white noise, the low frequency components of the AR(1) are more important than the high frequency components. Thus, realizations of the series appear smoother than white noise.

Spectral Estimation

There are two general approaches to estimating spectra. Perhaps the simplest is to estimate an ARMA model for the series (as explained in Time Series: ARIMA Methods) and then compute the implied spectrum for this estimated model. Asymptotic approximations can then be used for statistical inference. Since the estimators of the ARMA parameters are asymptotically normally distributed and the spectrum is a smooth function of these parameters (see eqn [11]), the estimated spectrum at any point ω will be asymptotically normal with a variance that can be computed using the δ-method (a mean-value expansion).

An interesting extension of this procedure is discussed in Berk (1974). He shows that, quite generally, a suitably long autoregression can be specified and the spectrum estimated using the estimated AR coefficients. The precise definition of 'suitably long' depends on the size of the available sample, with more terms included in larger samples. These 'autoregressive spectral estimators' are shown by Berk to be consistent and approximately normally distributed in large samples.

An alternative set of estimators are based on non-parametric methods. These estimators can be motivated by eqn [7] which shows the spectrum as a weighted sum of the autocovariances. This suggests an estimator of the form:

$$S(\omega) = (2\pi)^{-1}\sum_{k=-l_T}^{l_T} w_T(k)\widehat{\lambda}_k$$

where $\widehat{\lambda}_k$ is an estimator of λ_k, l_T are truncation values that depend on the sample size T, and $w_T(k)$ is a weight function that

also depends on T. These estimators can be studied using nonparametric methods (*see* Nonparametric Statistics: Asymptotics).

A closely related set of nonparametric estimators are based on the 'periodogram'. The periodgram provides a frequency decomposition of the sample variance of a partial realization of the process, say $\{Y_t\}_{t=1}^{T}$. The periodgram is computed at frequencies $\omega_j = 2\pi j/T, j = 1, 2, \ldots, T/2$ (assuming T is even), and the value of the periodgram at frequency ω_j, is:

$$p_j = \frac{2}{T}\left|\sum_{t=1}^{T}(y_t - \bar{y})e^{-i\omega_j t}\right|^2$$

The periodgram has three interesting asymptotic sampling properties: (1) $E(p_j)/4\pi \rightarrow S_Y(\omega_j)$; (2) $var(p_j/2\pi) \rightarrow S_Y(\omega_j)^2$; and (3) $cov(p_j, p_k) = 0$ for $j \neq k$. Property (1) shows that a scaled version of the periodgram provides an asymptotically unbiased estimator of the spectrum, but since the variance doesn't approach zero (property (2)), the estimator is not consistent. The third property shows that averaging a set of periodgram ordinates around a given frequency reduces the variance of the estimator, although (from property (1)) it may introduce bias. By carefully selecting the averaging weights, consistent estimators with good finite sample mean square error properties can be constructed.

Some recent advances for nonparametric spectral estimators are developed in Andrews (1991).

Abstract

Time-series forecasting uses historical empirical regularities, guided by a theoretical understanding of economic processes, to make future projections. Economic forecasts are used in a wide range of activities, including setting monetary and fiscal policies, state and local budgeting, financial management, and financial engineering. Key elements of economic forecasting include selecting the forecasting model(s) appropriate for the problem at hand, assessing and communicating the uncertainty associated with a forecast, and guarding against model instability.

Time-series forecasts are used in a wide range of economic activities, including setting monetary and fiscal policies, state and local budgeting, financial management, and financial engineering. Key elements of economic forecasting include selecting the forecasting model(s) appropriate for the problem at hand, assessing and communicating the uncertainty associated with a forecast, and guarding against model instability.

Time-Series Models for Economic Forecasting

Broadly speaking, statistical approaches to economic forecasting fall into two categories: time-series methods and structural economic models. Time-series methods use economic theory mainly as a guide to variable selection, and rely on past patterns in the data to predict the future. In contrast, structural economic models take as a starting point formal economic theory and attempt to translate this theory into empirical relations, with parameter values either suggested by theory or estimated using historical data. In practice, time-series models tend to be small with at most a handful of variables, while structural models tend to be large, simultaneous equation systems, which sometimes incorporate hundreds of variables (*see* Simultaneous Equation Estimation: Overview). Time-series models typically forecast the variable(s) of interest by implicitly extrapolating past policies into the future, while structural models, because they rely on economic theory, can evaluate hypothetical policy changes. In this light, perhaps it is not surprising that time-series models typically produce forecasts as good as, or better than, far more complicated structural models. Still, it was an intellectual watershed when several studies in the 1970s (reviewed in Granger and Newbold, 1986) showed that simple univariate time-series models could outforecast the large structural models of the day, a result that continues to be true (see McNees, 1990). This good forecasting performance, plus the relatively low cost of developing and maintaining time-series forecasting models, makes time-series modeling an attractive way to produce baseline economic forecasts.

At a general level, time-series forecasting models can be written,

$$y_{t+h} = g(X_t, \theta) + \varepsilon_{t+h} \qquad [1]$$

where y_t denotes the variable or variables to be forecast, t denotes the date at which the forecast is made, h is the forecast horizon, X_t denotes the variables used at date t to make the forecast, θ is a vector of parameters of the function g, and ε_{t+h} denotes the forecast error. The variables in X_t usually include current and lagged values of y_t. It is useful to define the forecast error in eqn [1] such that it has conditional mean zero, that is, $E(\varepsilon_{t+h}|X_t) = 0$. Thus, given the predictor variables X_t, under mean squared error loss the optimal forecast of y_{t+h} is its conditional mean, $g(X_t, \theta)$. Of course, this forecast is infeasible because in practice neither g nor θ is known. The task of the time-series forecaster therefore is to select the predictors X_t, to approximate g, and to estimate θ in such a way that the resulting forecasts are reliable and have mean squared forecast errors as close as possible to that of the optimal infeasible forecast.

Time-series models are usefully separated into univariate and multivariate models. In univariate models, X_t consists solely of current and past values of y_t. In multivariate models, this is augmented by data on other time series observed at date t. The next subsections provide a brief survey of some leading time-series models used in economic forecasting. For simplicity attention is restricted to one-step ahead forecasts ($h = 1$). Here, the focus is on forecasting in a stationary environment; the issue of nonstationarity in the form of structural breaks or time varying parameters is returned to below.

Univariate Models

Univariate models can be either linear, so that g is linear in X_t, or nonlinear. All linear time-series models can be interpreted as devices for modeling the covariance structure of the data. If $\{y_t\}$, $t = 1, \ldots, T$ has a Gaussian distribution and if this distribution is stationary (does not depend on time), then the optimal forecast is a linear combination of past values of the data with constant weights. Different linear time-series models provide different parametric approximations to this optimal linear combination.

The leading linear models are autoregressive models, autoregressive integrated moving average (ARIMA) models, and unobserved components models.

An autoregressive model of order p [AR(p)] is written,

$$y_{t+1} = \mu + \alpha_1 y_t + \cdots + \alpha_p y_{t-p+1} + \varepsilon_{t+1} = \mu + \alpha(L) y_t + \varepsilon_{t+1}$$

where (μ, α_1, …, α_p) are unknown parameters, L is the lag operator, and $\alpha(L)$ is a lag polynomial. If y_t is observed at all dates, $t = 1, \ldots, T$, these parameters are readily estimated by ordinary least squares.

ARIMA models extend autoregressive models to include a moving average term in the error, which has the effect of inducing long lags in the forecast when it is written as a function of current and past values of y_t. These are discussed in Time Series: ARIMA Methods.

In an unobserved components model, y_t is represented as the sum of two or more different stochastic components. These components are then modeled, and the combined model provides a parametric approximation to the autocovariances; see Harvey (1990) for a detailed modern treatment. The unobserved components framework can provide a useful framework for extracting cyclical components of economic time series and for seasonal adjustment (*see* Time Series: Seasonal Adjustment).

If $\{y_t\}$ is not Gaussian, in general, the optimal forecast will not be linear, which suggests the use of forecasts based on nonlinear time-series models. Parametric nonlinear time-series models posit a functional form g, and take this as known up to the finite dimensional parameter vector θ. Two leading examples of parametric nonlinear time-series models, currently popular for economic forecasting, are threshold autoregressive models and Markov switching models. Both are similar in the sense that they posit two (or more) regimes. In the threshold autoregression, switches between the regimes occur based on past values of the observed data; in Markov switching models, the switches occur based on an unobserved or latent variable.

The threshold autoregressive family of models can be written as,

$$y_{t+1} = d_t\alpha(L)y_t + (1 - d_t)\beta(L)y_t + \varepsilon_{t+1} \qquad [2]$$

where the mean is suppressed, $\alpha(L)$ and $\beta(L)$ are lag polynomials, and d_t is a nonlinear function of past data that switches between the 'regimes' $\alpha(L)$ and $\beta(L)$. Variations of eqn [2] interact d_t with only some autoregressive coefficients, the intercept, and/or the error variance. Various functions are available for d_t, either a sharp indicator function (the threshold autoregressive model) or a smooth function (smooth transition autoregression). For example, setting $d_t = [1 + \exp(\gamma_0 + \gamma_1'\zeta_t)]^{-1}$, yields the logistic smooth transition autoregression (LSTAR) model, where ζ_t denotes current or past data, say, ζ_t might equal y_{t-k} for some k. See Granger and Teräsvirta (1993) for additional details. For an application of threshold autoregressions (and other models) to forecasting the US unemployment, see Montgomery et al. (1998).

The Markov switching models are conceptually similar, except that the regime switch depends on an unobserved series. In the context of eqn [2], d_t is modeled as unobserved and following a two-state Markov process; see Hamilton (1994).

An alternative approach is to treat g itself as unknown, which leads to nonparametric methods. These include nearest neighbor, kernel, and artificial neural network models for the conditional expectation. In practice these nonparametric approaches to economic forecasting have met with success, which is mixed at best. There are several possible reasons for this, including that there are insufficiently many observations in typical economic data sets to support the use of these data-intensive methods.

Multivariate Models

In multivariate time-series models, X_t includes multiple time-series that can usefully contribute to forecasting y_{t+1}. The choice of these series is typically guided by both empirical experience and economic theory, for example, the theory of the term structure of interest rates suggests that the spread between long- and short-term interest rates might be a useful predictor of future inflation.

The multivariate extension of the univariate autoregression is the vector autoregression (VAR), in which a vector of time-series variables, Y_{t+1}, is represented as a linear function of $Y_t, \ldots, Y_{t-p+1}$, perhaps with deterministic terms (an intercept or trends). An interesting possibility arises in VARs that is not present in univariate autoregressions, specifically, it might be that the time series are cointegrated (that is, the individual series are nonstationary in the sense that they are integrated, but linear combinations of the series are integrated or order zero); *see* Times Series: Cointegration and Watson (1994).

Multivariate time-series models involve a large number of unknown parameters, a problem, which is greatly exacerbated when nonlinearities are introduced. Conceptually, the extension of univariate nonlinear models to the multivariate setting is straightforward. In practice, however, because of the relatively small number of time-series observations available to economic forecasters, it is unclear how best to implement nonlinear multivariate models and there are currently no definite conclusions in this area.

Models for Forecasting Higher Moments

The foregoing categorization of forecasting models has focused on prediction of conditional means. In some economic applications, especially in financial economics, interest is also in forecasting conditional higher moments. The most developed tools in this area are models of conditional variances. Two families of such models are autoregressive conditional heteroskedasticity models (Engle, 1982; see Bollerslev et al., 1994) and stochastic volatility models. Both approaches provide parametric models for the volatility of the series, which can then be forecasted given parameters estimated from historical data.

When Do Time-Series Forecasts Fail?

Regrettably, only by luck will economic forecasts be 'right': there are inevitable sources of uncertainty that make perfectly accurate predictions of the future impossible.

Shock, Model, and Estimation Uncertainty

Sources of uncertainty that comprise the error term ε_{t+h} in eqn [1] ('shock uncertainty') consist of unknowable future events, random measurement error in the series being forecast, and unforeseeable data revisions. Additional forecast

uncertainty arises from model approximation error (that is, error in the choice of g) and from error in the estimation of the model parameters θ.

Sensible use of economic forecasts requires that this forecast uncertainty be accurately communicated. Prediction intervals can be computed either directly based on historically estimated parameters and residuals, or by simulation for more complicated nonlinear models. Ideally these prediction intervals should incorporate parameter estimation uncertainty. There are several ways to do this, but a natural one is to construct forecast error distributions using a simulated out of sample prediction methodology. In this approach, the model is estimated using data through some date, say t', then a forecast is made for the next period ($t' + h$, for h-step ahead forecasts). The model is then reestimated using data through date $t' + 1$, and the forecast is made for $t' + h + 1$. This is repeated until a series of simulated out-of-sample forecast errors is constructed, which, in turn, can be used to construct prediction intervals around the point forecast of interest.

Overfitting

Overfitting poses a particular threat in economic forecasting given the impossibility of creating new data sets through experiments and given the relatively short number of observations on many economic time series. Overfitting can be addressed in part by relying on automatic methods for pruning a model. Leading such methods is model selection using information criteria such as the Akaike or Bayes (*see* Model Testing and Selection, Theory of). Alternatives include Bayes or Empirical Bayes estimation. Combining forecasts by taking averages or weighted averages can also be interpreted as a method for addressing the overfitting that arises in model selection.

Difficulties Modeling Trends

An important characteristic of economic data is that many economic time series contain considerable persistence, sometimes resembling a trend. Starting with the seminal work of Nelson and Plosser (1982), there has been considerable debate about whether these trends are best modeled as deterministic or stochastic (that is, arising from unit autoregressive roots), see Stock (1994). If a forecasting model incorrectly incorporates deterministic trends, but the series is highly persistent, spuriously large weight can be placed on an estimated trend component and out-of-sample forecasts can suffer. Such considerations lead to the use of methods that explicitly address the possibilities of stochastic trends, an example being preliminarily testing for a unit root in a univariate time series and constructing a univariate model in levels or in differences depending on the outcome of the pretest.

Model Instability

Clements and Hendry (1999) argue that many major failures of economic forecasts arise because of structural breaks to which conventional forecasting models fail to adapt. In some cases, model instability can arise because of slow changes in parameter values, perhaps arising from evolution in underlying technologies in the economy. In other, more dramatic cases, model instability appears as a sudden break, such as a change in monetary policy or the collapse of an exchange rate regime.

Whether structural change is gradual or abrupt, it is critical to monitor forecast performance and to test for model instability. Various statistical methods are available for detecting structural change; these typically involve testing for evidence of instability either in estimated coefficients or in simulated forecast errors. In practice, these methods need to be augmented by expert judgment that draws on information not incorporated in the model, such as knowledge of particularly severe weather (which could lead to a structural break being spuriously detected) or of a known change in a policy regime (so a break might be imposed even if it is not detected statistically). Unfortunately, expert judgment can be wrong, and knowing when to intervene in an economic forecast is a rather murky art.

Which Methods Work Best?

It is perhaps overly ambitious to hope for a simple prescription that provides a good forecasting method for all economic time series. Nonetheless, a number of studies have attempted to provide some general guidance on this question. Two general lessons emerge: among univariate models, simple linear models often forecast as well or better than more complicated nonlinear models; and the gains from moving from univariate to multivariate models are often (but not always) small.

This is illustrated by forecasts of the rate of price inflation over 6 months in the United States, as measured by the percentage rate of inflation of the Consumer Price Index (this example is taken from Stock and Watson's (1999) comparison of linear and nonlinear forecasting models for 215 US macroeconomic time series). Simulated out of sample, 6-month-ahead forecasts over the period March 1971–June 1996 (the full sample begins January 1959) produce a root mean square forecast error (RMSFE) of 2.44 percentage points (at an annual rate) for a univariate AR(4) fit recursively to the annualized rate of inflation. If the autoregressive lag length is selected recursively using the Bayes information criterion and a recursive unit root protest is used to determine whether the autoregression is fit to the rate of inflation or the change in the rate, the RMSFE drops to 2.05. Forecasts based on artificial neural networks and LSTAR models have RMSFEs exceeding 2.15 and in some cases exceeding 2.5, depending on the specification. A VAR that adds the unemployment rate and short-term interest rate (recursive Bayes information criterion lag selection) produces an RMSFE of 2.31. For these models, then, introducing nonlinearity or adding these other predictors does not improve upon a simple autoregression with a unit root pretest and data-dependent lag length selection.

The future of economic forecasting promises the development of new, computer-intensive methods and the real-time availability of very large data sets with complex patterns of historical dependence. These developments could prove invaluable for advancing economic forecasting, and the lessons from the past four decades of economic forecasting might not extend to these new data sets. Yet those lessons do underscore

the importance of having a simple and reliable benchmark forecast against which alternative forecasts can be assessed.

Abstract

A time series is a stretch of values on the same scale indexed by a time-like parameter. The basic data and parameters are functions. Time series take on a dazzling variety of shapes and forms, indeed there are as many time series as there are functions of real numbers.

A *time series* is a stretch of values on the same scale indexed by a time-like parameter. The basic data and parameters are functions.

Time series take on a dazzling variety of shapes and forms, indeed there are as many time series as there are functions of real numbers. Some common examples of time series forms are provided in **Figure 1**. One notes periods, trends, wandering, and integer values. The time series such as those in the figure may be contemporaneous and a goal may be to understand the interrelationships.

Concepts and fields related to time series include longitudinal data, growth curves, repeated measures, econometric models, multivariate analysis, signal processing, and systems analysis.

The field, time series analysis, consists of the techniques, which when applied to time series lead to improved knowledge. The purposes include summary, decision, description, and prediction.

The field has a theoretical side and an applied side. The former is part of the theory of stochastic processes (e.g., representations, prediction, information, limit theorems) while applications often involve extensions of techniques of 'ordinary' statistics, for example, regression, analysis of variance, multivariate analysis, and sampling. The field is renowned for jargon and acronyms – white noise, cepstrum, *autoregressive moving average* (ARMA), ARCH (see Granger, 1982).

Importance

> … but time and chance happeneth to them all.
> *Ecclesiastes*

Time series ideas appear basic to virtually all activities. Time series are used by nature and humans alike for communication, description, and visualization. Because *time* is a physical concept, parameters and other characteristics are mathematical models for time series can have real-world interpretations. This is of great assistance in the analysis and synthesis of time series.

Time series are basic to scientific investigations. There are: circadian rhythms, seasonal behaviors, trends, changes, and evolving behavior to be studied and understood. Basic questions of scientific concern are formulated in terms of time series concepts – Predicted value? Leading? Lagging? Causal connection? Description? Association? Autocorrelation? Signal? Seasonal effect? New phenomenon? Control? Periodic? Changing? Trending? Hidden period? Cycles?

Because of the tremendous variety of possibilities, substantial simplifications are needed in many time series analyses. These may include assumptions of stationarity, mixing or asymptotic independence, normality, and linearity. Luckily such assumptions often appear plausible in practice.

The subject of time series analysis would be important if for no other reason than that it provides means of examining the basic assumption of statistical independence invariably made in ordinary statistics. One of the first commonly used procedures for this problem was the Durbin–Watson test (Durbin and Watson, 1950). The autocovariance and spectrum functions, see below, are now often used in this context.

History

Contemporary time series analysis has substantial beginnings in both the physical and social sciences. Basic concepts have appeared in each subject and made their way to the other with consequent transfer of technology. Historical researchers important in the development of the field include the following: Lauritzen (1981), Hooker (1901), Einstein (1914), Wiener (1949), Yule (1927), Fisher (1929), Tukey (1984), Whittle (1951), and Bartlett (1966). Books particularly influential in the social sciences include Moore (1914) and Davis (1941). Nowadays many early analyses appear naive. For example, Beveridge in 1920 listed some 19 periods for a wheat price index running from 1500 to 1869 (Beveridge, 1922). It is hard to imagine the presence of so much regular behavior in such a series. When statistical uncertainty is estimated using latter-day techniques most of these periods appear insignificant; see the periodogram with 95% error bounds in **Figure 2**. Many historical references are included in Wold (1965).

Historians of science have made some surprising discoveries concerning early work with time series. An example is presented in Tufte (1983). He shows a time series plot from the tenth- or eleventh-century AD. This graph is speculated to provide movements of the planets and sun. It is remarkable for its cartesian type character. More generally Tufte remarks, following a study of newspapers and magazines, that "The time-series plot is the most frequently used form of graphic design." Casual observation certainly supports Tufte's study.

Figure 1 Some different types of time series.

Important problems that were addressed in the twentieth century include seasonal adjustment, leading and lagging indicators, and index numbers. Paradigms that were developed include:

$$\text{series} = \text{signal} + \text{noise}$$

$$\text{series} = \text{trend} + \text{seasonal} + \text{noise}$$

$$\text{series} = \text{sum of cosines} + \text{noise}$$

$$\text{series} = \text{regression function} + \text{noise}$$

These conceptualizations have been used for forecasting, seasonal adjustment, and description among other things. There are surprises, for example, ordinary least squares are surprisingly efficient in the time series case (see Grenander and Rosenblatt, 1957). Other books from the 1950s and 1960s that proved important are Blackman and Tukey (1959), Granger and Hatanaka (1964), and Box and Jenkins (1970). Important papers from the era include Akaike (1965), Hannan (1963), and Parzen (1961).

An important development that began in the 1950s and continues today is the use of recursive computation in the state space model; see Kalman (1963), Harvey (1990), Shumway and Stoffer (2000), and Durbin and Koopman (2001).

Basics

Concepts

There are a number of concepts that recur in time series work. Already defined is the *time series*, a stretch of values on the same scale indexed by a time parameter. The time parameter may range over the positive and negative integers or all real numbers or subsets of these. *Time series data* refer to a segment of a time series. A time series is said to have a *trend* when there is a slowly evolving change. It has a *seasonal* component when some cyclic movement of period 1 year is present. (The *period* of a cyclic phenomenon is the amount of time for it to repeat itself. Its *frequency* is the reciprocal of the period.)

There is an algebra of mathematical operations that either nature or an analyst may apply to a time series $\{X(t)\}$ to produce another series $\{Y(t)\}$. Foremost is the *filter*, or *linear*

Figure 2 The dashed lines provide 95% bounds about a central curve.

time invariant operation or *system*. In the case of discrete equispaced time this may be represented as

$$Y(t) = \sum_u a(u)X(t-u)$$

t, $u = 0, \pm 1, \ldots$. An example is the running mean used to smooth a series. The functions $X(.)$, $Y(.)$ may be vector-valued and $a(.)$ may be matrix-valued. In the vector-valued case feedback may be present. The sequence $\{a(u)\}$ is called the *impulse response function*. The operation has the surprising property of taking a series of period P into a series of the same period P. The filter is called *realizable* when $a(u) = 0$ for $u < 0$. Such filters appear in causal systems and when the goal is prediction.

The above ideas concern both deterministic and random series. The latter prove to be important in developing solutions to important problems. Specifically it often proves useful to view the subject of time series as part of the general theory of stochastic processes, that is, indexed families of random variables. One writes $\{Y(t, \omega), t \text{ in } V\}$, with ω a random variable and V a set of times. Time series data are then viewed as a segment, $\{Y(t, \omega_0), t = 0, \ldots, T-1\}$ of the realization labeled by ω_0, the obtained value of ω. Stochastic time series $\{Y(t), t = 0, \pm 1, \pm 2, \ldots\}$ sometimes are conveniently described by *finite dimensional distributions* such as

$$\text{Prob}\{Y(t) \le y\} \text{ and } \text{Prob}\{Y(t_1) \le y_1, Y(t_2) \le y_2\}$$

This is particularly the case for time series values with joint normal distributions.

Time series may also be usefully described or generated by stochastic models involving the independent identically distributed random variables of ordinary statistics.

Stochastic models may be distinguished as parametric or nonparametric. Basic parameters of the nonparametric approach include moments, joint probability and density functions, mean functions, autocovariance and cross-covariance functions, and power spectra.

One basic assumption of time series analysis is that of *stationarity*. Here the choice of time origin does not affect the statistical properties of the process. For example, the mean level of a stationary series is constant. Basic to time series analysis is handling temporal dependence. To this end one can define the *cross-covariance function* of the series X and Y at lag u as the covariance of the values $X(t+u)$ and $Y(t)$. In the stationary case this function does not depend on t. In an early paper, Hooker (1901) computed an estimate of this quantity. Another useful parameter is the *power spectrum*, a display of the intensity or variability of the phenomenon versus period or frequency. It may be defined as the Fourier transform of the autocovariance function. The power spectrum proves useful in displaying the serial dependence present, in discovering periodic phenomena and in diagnosing possible models for a series.

In the parametric case there are the ARMA series. These are regression-type models expressing the value $Y(t)$ as a linear function of a finite number of past values $Y(t-1)$, $Y(t-2)$, … of the series and the values $\varepsilon(t)$, $\varepsilon(t-1)$, … of a sequence of independent identically distributed random variables. ARMAs have proved particularly useful in problems of forecasting.

Contemporary models for time series are often based upon the idea of *state*. This may be defined as the smallest entity summarizing the past history of the process. There are two parts to the state space model. First, a state equation that describes how the value of the state evolves in time. This equation may contain a purely random element. Second there is an equation indicating how the available measurements at that time t come from the state value at that time. It too may involve a purely random element. The concept of the state of a system has been basic to

physics for many years in classical dynamics and quantum mechanics. The idea was seized upon by control engineers, for example, Kalman (1963) in the late 1950s. The econometricians realized its usefulness in the early 1980s (see Harvey, 1990).

A number of specific probability models have been studied in depth, including the Gaussian, the ARMA, the bilinear (Granger and Andersen, 1978), various other nonlinear (Tong, 1990), long and short memory, ARMAX, ARCH (Einstein, 1914), hidden Markov (MacDonald and Zucchini, 1997), random walk, stochastic differential equations (Guttorp, 1995; Prakasa Rao, 1999), and the periodically stationary.

A list of journals where these processes are often discussed is included at the end of this article.

Problems

There are scientific problems and there are associated statistical problems that arise. Methods have been devised for handling many of these. The scientific problems include smoothing, prediction, association, index numbers, feedback, and control. Specific statistical problems arise directly. Among these are including explanatories in a model, estimation of parameters such as hidden frequencies, uncertainty computation, goodness of fit, and testing.

Special difficulties arise. These include missing values, censoring, measurement error, irregular sampling, feedback, outliers, shocks, signal-generated noise, trading days, festivals, changing seasonal pattern, aliasing, data observed in two series at different time points.

Particularly important are the problems of association and prediction. The former asks the questions of whether two series are somehow related and what is the strength of any association. Measures of association include the cross-correlation and the coherence functions. The prediction problem concerns the forecasting of future values. There are useful mathematical formulations of this problem but because of unpredictable human intervention there are situations where guesswork seems just as good.

Theoretical tools employed to address the problems of time series analysis include mathematical models, asymptotic methods, functional analysis, and transforms.

Methods

Descriptive

Descriptive methods are particularly useful for exploratory and summary purposes. They involve graphs and other displays, simple statistics such as means, medians, and percentiles, and the techniques of exploratory data analysis (Tukey, 1977).

The most common method of describing a time series is by presenting a graph, see **Figure 1**. Such graphs are basic for communication and assessing a situation. There are different types. Cleveland (1985) mentions the connected, symbol, connected-symbol, and vertical-line displays in particular. **Figure 1** presents connected graphs.

Descriptive values derived from time series data include extremes, turning points, level crossings, and the periodogram (see **Figure 2** for an example of the latter). Descriptive methods typically involve generating displays using manipulations of time series data via operations such as differencing, smoothing, and narrowband filtering.

A display with a long history (Laplace, 1825; Wold, 1965) is the Buys Ballot table. Among other things it is useful for studying the presence and character of a phenomenon of period P such as a circadian rhythm. One creates a matrix with entry $Y[(i-1)P+j]$ in row i, column $j = 1, \ldots, P$ and then, for example, one computes column averages. These values provide an estimate of the effect of period P. The graphs of the individual rows may be stacked beneath each other in a display. This is useful for discerning slowly evolving behavior.

Descriptive methods may be time-side (as when a running mean is computed), frequency-side (as when a periodogram is computed), or hybrid (as when a sliding window periodogram analysis is employed).

Parameter Estimation

The way to a solution of many time series problems is via the setting down of a stochastic model. Parameters are constants of unknown values included in the model. They are important because substantial advantages arise when one works within the context of a model. These advantages include estimated standard errors, efficiency, and communication of results. Often parameter estimates are important because they are fed into later procedures, for example, formulas for forecasting.

General methods of estimating parameters include method of moments, least squares, and maximum likelihood. An important time series case is that of harmonic regression. It was developed in Fisher (1929) and Whittle (1951).

There are parametric and nonparametric approaches to estimation. The parametric has the advantage that if the model is correct, then the estimated coefficients have considerably smaller standard errors.

Uncertainty Estimation

Estimates without some indication of their uncertainty are not particularly useful in practice. There are a variety of methods used in time series analysis to develop uncertainty measures. If maximum likelihood estimation has been used there are classic (asymptotic) formulas. The delta method or method of linearization is useful if the quantity of interest can be recognized to be a smooth function of other quantities whose variability can be estimated directly. Methods of splitting the data into segments, such as the jackknife, can have time series variants. A method currently enjoying considerable investigation is the bootstrap (Davison and Hinkley, 1997). The assumptions made in validating these methods are typically that the series involved is stationary and mixing.

Seasonal Adjustment

Seasonal adjustment may be defined as the attempted removal of obscuring unobservable annual components. There are many methods of seasonal adjustment (National Bureau of Economic Research, 1976), including state space approaches (Hannan, 1963).

The power spectrum provides one means of assessing the effects of various suggested adjustment procedures.

System Identification

System identification refers to the problem of obtaining a description or model of a system on the basis of a stretch of input to and the corresponding output from a system of interest. The system may be assumed to be linear time invariant as defined above.

In designed experiments the input may be a series of pulses, a sinusoid, or white noise. In a natural experiment the input is not under the control of the investigator and this leads to complications in the interpretation of the results. System identification relates to the issue of causality. In some systems one can turn the input off and on and things are clearer.

Computing

Important computer packages for time series analysis include Splus, Matlab, Mathematica, SAS, SPSS, TSP, and STAMP. Some surprising algorithms have been found: the fast Fourier transform (FFT), fast algorithms from computational geometry, Monte Carlo methods, and the Kalman–Bucy filter. Amazingly a variant of the latter was employed by Thiele in 1880 (Lauritzen, 1981), while the FFT was known to Gauss in the early 1800s (Heideman et al., 1984).

Current Theory and Research

Much of what is being developed in current theory and research is driven by what goes on in practice in time series analyses. What is involved in a time series analysis? The elements include the question, the experiment, the data, plotting the data, the model, model validation, and model use. The importance of recognizing and assessing the basic assumptions is fundamental.

The approach adopted in practice often depends on how much data are available. In the case that there are a lot of data even procedures that are, in some sense, inefficient are often used effectively. A change from the past is that contemporary analysis often results from the appearance of very large fine data sets. The amount of data can seem limitless as, for example, in the case of records of computer tasks. There are many hot research topics. One can mention: exploratory data analysis techniques for very large data sets, so-called improved estimates, testing (association? cycle present?), goodness of fit diagnostics. There are the classical and Bayesian approaches, the parametric, semiparametric, and nonparametric analyses, the problem of dimension estimation and that of reexpression of variables.

Current efforts include research into bootstrap variants, long-memory processes, long-tailed distributions, non-Gaussian processes, unit roots, nonlinearities, better approximations to distributions, demonstrations of efficiency, self-similar processes, scaling relationships, irregularly observed data, doubly stochastic processes as in hidden Markov, cointegration, disaggregation, cyclic stationarity, wavelets, and particularly inference for stochastic differential equations.

Today's time series data values may be general linear model type (Fahrmein and Tutz, 1994), for example, ordinal, state-valued, counts, proportions, angles, and ranks. They may be vectors. They may be functions. The time label t may be location in space or even a function. The series may be vector-valued. The data may have been collected in an experimental design.

There are some surprises: the necessity of tapering and prewhitening to reduce bias, the occurrence of aliasing, the high efficiency of ordinary least squares estimates in the correlated case, and the approximate independence of empirical Fourier transform values at different frequencies (Brillinger, 1975).

Future Directions

It seems clear that time series research will continue on all the existing topics as the assumptions on which any existing problem solution has been based appear inadequate. Further, it can be anticipated that more researchers from nontraditional areas will become interested in the area of time series as they realize that the data they have collected, or will be collecting, are correlated in time.

Researchers can be expected to be even more concerned with the topics of nonlinearity, conditional heteroscedasticity, inverse problems, long memory, long tails, uncertainty estimation, inclusion of explanatories, new analytic models, and properties of the estimates when the model is not true. The motivation for the latter is that time series with unusual structure seem to appear steadily. An example is the data being collected automatically via the World Wide Web. Researchers can be anticipated to be seeking extensions of existing time series methods to processes with more general definitions of the time label – spatial, spatial-temporal, functional, and angular. At the same time they will work on processes whose values are more general, even abstract.

More efficient, more robust, and more applicable solutions will be found for existing problems. Techniques will be developed for dealing with special difficulties such as missing data, nonstationarity, and outliers. Better approximations to the distributions of time series–based statistics will be developed.

Many have stressed the advantages of linear system identification via white noise input. Wiener (1958) stressed the benefits of using Gaussian white noise input. This idea has not been fully developed. Indeed data sets obtained with this input will continually yield to novel analytic methods as they make their appearance.

The principal journals in which newly developed statistical methods for time series are presented and studied include *Journal of Time Series Analysis*, *Annals of Statistics*, *Stochastic Processes and their Applications*, *Journal of the American Statistical Association*, *Econometrica*, and *IEEE Transactions in Signal Processing*.

Abstract

This article discusses the main characteristics of seasonal variations, common statistical seasonal models and the seasonal adjustment methods widely applied by statistical agencies. Seasonal adjustment means the removal of seasonal variations and plays a significant role in standardizing time series for the analysis of current social and economic conditions, particularly in determining the stages of the business cycle at which the economy stands. Such knowledge provides the bases for decision making to control the level of economic activity and it is of major importance around cyclical turning points.

The best known *seasonal adjustment methods* belong to the following types: (1) regression methods which assume *global or local* simple functions of time, (2) *stochastic-model-based* methods which assume simple autoregressive integrated moving average (ARIMA) models, and (3) moving average methods which are based on linear filtering and hence do not have *explicit parametric* models. Moving average and ARIMA model based methods are those applied by statistical agencies to produce officially seasonally adjusted series.

Introduction

A time series consists of a set of observations ordered in time, on a given phenomenon (target variable). Usually the measurements are equally spaced, e.g., by year, quarter, month, week, day. The most important property of a time series is that the ordered observations are dependent through time, and the nature of this dependence is of interest in itself. Examples of time series are the gross national product, the unemployment rate, or the daily closing value of the Dow Jones index.

Time series of sub-yearly observations, e.g., monthly, quarterly, weekly, are often affected by seasonal variations. The presence of such variations in socio–economic activities has been recognized for a long time. Indeed seasonality usually accounts for most of the total variation within the year.

Seasonality is due to the fact that some months or quarters of the year are more important in terms of activity or level. This originates from climate and conventional seasons, like religious, social, and civic events, which repeat from year to year.

The climatic seasons influence trade, agriculture, the consumption patterns of energy, fishing, mining, and related activities. For example, in North America, the level of unemployment is generally higher during the winter and spring months and lower in the other months. Similarly, the consumption of heating oil increases in winter, and the consumption of electricity increases in the summer months because of air conditioning.

Institutional seasons like Christmas, Easter, civic holidays, the school and academic year have a large impact on employment, retail trade and on the consumption of certain goods and services, namely travel by plane, hotel occupancy, consumption of gasoline.

Yearly series cannot contain seasonality because the component is specified to cancel out over 12 consecutive months or 4 consecutive quarters.

Flow series may also be affected by other kind of seasonal variations associated with the composition of the calendar. The most important calendar variations are the trading-day variations, which are due to the fact that some days of the week are more important than others. Trading-day variations imply the existence of a daily pattern analogous to the seasonal pattern but these daily factors are usually referred to as *daily coefficients*.

Similarly, the *moving-holiday* or *moving-festival* component is attributed to calendar variations, namely due to the fact that some holidays span consecutive months from year to year. For example, Easter can fall between 23 March and 25 April. These festivals affect flow and stock variables and may cause a displacement of activity from 1 month to the previous or the following month. For example, an early date of Easter in March or early April can cause an important excess of activity in March and a corresponding short-fall in April, in variables associated to imports, exports, and tourism. When the Christian Easter falls late in April (e.g., beyond the 10th), the effect is captured by the seasonal factor of April. Note that in the long run, Easter falls in April 11 times out of 14.

Seasonal adjustment means the removal of seasonal variations in the original series jointly with trading day variations and moving holiday effects. The main reason for seasonal adjustment is the need of standardizing socioeconomic series because seasonality affects them with different timing and intensity. Hence, the seasonally adjusted data reflect variations due only to the remaining components, namely trend-cycle and irregulars.

The information given by seasonally adjusted series plays a crucial role in the analysis of current economic conditions and provides the basis for decision making and forecasting, being of major importance around cyclical turning points.

Seasonal methods can be classified as *deterministic* or *stochastic* depending on the assumptions made concerning how seasonality evolves through time. *Deterministic* methods assume that the seasonal pattern can be predicted with no error or with zero variance of the prediction error. On the contrary, *stochastic* methods assume that seasonality can be represented by a *stochastic process*, a process governed by a probability law and, consequently, the variance of the prediction error is not null. The best known *seasonal adjustment methods* belong to the following types: (1) regression methods which assume *global or local* simple functions of time, (2) *stochastic-model-based*

methods which assume simple autoregressive integrated moving average (ARIMA) models, and (3) moving average methods which are based on linear filtering and hence do not have *explicit parametric* models. Only methods (1), which assume *global* simple functions for each component, are *deterministic*; the others are considered *stochastic*. Moving average or linear filtering methods are those applied mostly by statistical agencies to produce officially seasonally adjusted series.

This article discusses the main characteristics of seasonal variations, common statistical seasonal models and the seasonal adjustment methods widely applied by statistical agencies.

The Main Characteristics of Seasonality

The impact of seasonality in socioeconomic activities has long been recognized. Seasonal variations in agriculture, the low level of winter construction and high pre-Christmas retail sales are all well known.

The main causes of seasonality are mainly exogenous to economic systems but human intervention can modify their extent and nature. Thus, seasonal variations in the automobile industry are affected by manufacturers' decisions regarding the extent of model changeover each year; seasonality in the money supply and related series can be controlled by central banks' decisions on the interest rate. Another characteristic of seasonal variations is that although they repeat annually with certain regularity, they may evolve. Many causes can produce an evolving seasonality, for example, changes in technology alter the importance of climatic factors; customs and habits are affected by different distributions of income and thus, can modify the seasonal demand pattern for certain goods. For most time series, moving seasonality is more the rule than the exception. Depending on the main causes of the seasonal variations, these can change slowly or rapidly, in a deterministic or a stochastic manner or a mixture of both. A third important feature of seasonality is the feasibility of its identification even if it is a latent (non-directly observable) variable. The identification and estimation of seasonality, however, is not done independently of the other components affecting the series under study. Traditionally, three other components have been distinguished, namely; the trend, the cycle, and the irregulars. The trend reflects long term movements lasting many years. It is generally associated with structural causes, for example, institutional events, demographic and technological changes, new ways of organization. The cycle, usually referred to as business cycle, is a quasi-periodic oscillation characterized by periods of expansion and contraction. It lasts from 3 to 5 years on average. In much analytical work, the trend and the cycle are combined because, for series covering a short period of time, the long-term trend cannot be estimated adequately. Finally, the irregulars represent unforeseeable movements related to events of all kinds. In general, the irregular component has a stable random appearance but, in some cases, it may include extreme variations or outliers with well identifiable causes, for example, floods, severe winters, strikes.

The seasonal variations can be distinguished from the trend by their oscillatory character, from the business cycle by having annual periodicity and from the irregulars by being systematic. The four main causes of seasonality are attributed to the weather, composition of the calendar, major institutional deadlines and expectations. The changing industrial mix of an economy transforms the seasonal pattern because some industries are more seasonal than others. In particular, economies which diversify and depend less on 'primary' industries (e.g., fishing, agriculture) typically become less seasonal. As for institutional change, the extension of the academic year to the summer months in the 1970s affected the seasonal pattern of Canada unemployment for the population of 15–25 years of age. Similarly the practice of spreading holidays over the whole year impacted on seasonality.

The seasonal pattern basically repeats from year to year. Merely repeating the seasonal pattern of the last 12 months usually provides a reasonable forecast but in most situations, seasonality evolves even though slowly and gradually.

Another important characteristic of seasonality is the feasibility of its identification even if it is a latent (not directly observable) variable. The identification and estimation of seasonality, however, is not done independently of the other components affecting the time series under study, trend, business cycle, trading day variations, moving holidays and irregulars.

In order to determine whether a series contains seasonality, it is sufficient to identify at least 1 month (or quarter) which tends to be systematically higher or lower than other month.

For illustrative purposes, Figure 1 shows the pattern of an observed time series (US Unemployed Males, from January 1990 till December 2013) which is affected strongly by both seasonality and the business cycle, but their effects cannot be clearly inferred by simply looking at the graph.

The various components are shown in Figures 2–4. Figure 2 exhibits the seasonal variations that are characterized by two peaks and one trough. A large peak is observed in January when unemployment is highest and a small secondary one in June when young people have left school and look for work whereas the trough corresponds to the month of September.

Seasonality entails large costs to society and businesses. One cost is the necessity to build warehouses to store inventories of goods to be sold as consumers require them, for example grain elevators. Another cost is the under-use and over-use of the factors of production: capital and labor.

Capital in the form of un-used equipment, buildings and land during part of the year has to be financed regardless. For example, this is the case in farming, food processing, tourism, electrical generation. The cold climate increases the cost of buildings and infrastructure, e.g., roads, transportation systems, water and sewage systems, schools, hospitals; not to mention the damage to the same caused by the action of ice.

The labor force is over-used during the peak seasons of agriculture and construction for example; and, under-used in trough seasons sometimes leading to social problems.

The seasonal pattern measures the relative importance of the months of the year. The constant 100% represents an average month or a non-seasonal month. The *peak* month in January 1990 is 117.5 or 17.5% larger than on an average month; the *trough* months is September with 89.3 in 1990, almost 11% lower than on an average month. The *seasonal amplitude*, the difference between the peak and trough months of the seasonal pattern, has changed from 28.5% in 1990 to

Figure 1 Original series (thousands) US unemployment level – Male.

Figure 2 Seasonal factors (%) US unemployment level – Male.

15% in 2013. It is apparent that the seasonal amplitude is decreasing since 2003.

The effects of the trend-cycle are shown in Figure 3 with three large jumps in 1992, 2003, and 2009 which are recession years. The irregulars exhibited in Figure 4 are generally small except for a few cases where extreme values are present. Finally, the seasonally adjusted data are shown in Figure 5 clearly indicating that the impact of seasonality has been removed from the original series. The seasonally adjusted series contains the effects of the trend-cycle and those of the irregular component and, therefore, it is less smooth than the trend-cycle shown in Figure 3.

Seasonal Adjustment Methods

The seasonal adjustment methods developed so far are based on univariate time series decomposition models with no causal explanation. It is difficult to classify existing methods into mutually exclusive categories. However, it is possible to group the majority of seasonal adjustment methods into two main classes, one based on moving averages or linear filters and the other on explicit models with a small number of parameters for each component.

Moving Average Methods

The best known and most often applied seasonal adjustment methods are based on moving averages or smoothing linear filters applied sequentially by adding (and subtracting) one observation at a time. These methods assume that the time series components change through time in a stochastic manner. Given a time series, x_t, $t = 1, \ldots, T$, for any t far removed from both ends, say $m + 1 \leq t \leq T - m$, the seasonally adjusted value x_t^a, is obtained by application of a symmetric moving average h_m (B) applied to $2m + 1$ observations surrounding the target point t, x_{t+j}, $j = -m, \ldots, m$

$$x_t^a = h_m(\mathrm{B})x_t = \sum_{j=-m}^{m} h_{m,j} x_{t-j} \qquad [1a]$$

Figure 3 Trend-cycle component (thousands) US unemployment level – Male.

Figure 4 Irregular component (%) US unemployment level – Male.

Figure 5 Seasonally adjusted series (thousands) US unemployment level – Male.

where the weights $h_{m,j}$ are symmetric, that is $h_{m,j} = h_{m,-j}$, and the length of the average is $2m+1$.

For current and recent data $(T-m < t \leq T)$ a symmetric linear filter cannot be applied, and therefore truncated asymmetric filters are used. For example, for the last available observation x_T, the seasonally adjusted value is given by

$$x_T^a = h_0(B)x_T = \sum_{j=0}^{m} h_{0j}x_{T-j} \qquad [1b]$$

The asymmetric filters are time varying in the sense that different filters are applied for the $m+1$ first and last observations. The end estimates revised as new observations are added because of: (1) the new innovations, and (2) the differences between the symmetric and asymmetric filters. The estimates obtained with symmetric filters are often called 'final.'

The development of electronic computers contributed to major improvements in seasonal adjustment based on moving averages and facilitated their massive application.

In 1954, Julius Shiskin of the US Bureau of Census developed software called Method I, based mainly on the works of Macaulay (1931) already being used by the US Federal Reserve Board. Census Method I was followed by Census Method II and 11 more experimental versions (X1, X2, …, X11). The best known and widely applied was the Census X11 variant (Shiskin et al., 1967) but produced poor seasonally adjusted data at the end of the series which is of crucial importance to assess the direction of the short-term trend and the identification of turning points in the economy.

Dagum (1978) developed the X11ARIMA to correct for this serious limitation. The X11ARIMA method consists of: (1) modeling the original series with an ARIMA model of the Box and Jenkins (1970) type, (2) extending the original series 1–3 years with forecasts from the ARIMA model that fits and extrapolate well according to well defined acceptance criteria, and (3) estimating each component with moving averages that are symmetric for middle observations and asymmetric for both end years. The latter are obtained via the convolution of Census X11 variant and the ARIMA model extrapolations. For flow series, deterministic components such as trading-day variations and Easter holiday effects are estimated with dummy variable regression models and removed from the series, so that only the remainder is subject to steps (1) to (3) above. The X11ARIMA was extended again by Dagum (1988) and, later Findley et al. in 1998 developed X12ARIMA that offers a RegARIMA option to estimate deterministic components such as trading day variations and Moving Holiday effects simultaneously with the ARIMA model for extrapolation. It also includes new diagnostic tests and spectral techniques to assess the goodness of the results. The X12ARIMA method is today the one most often applied by statistical agencies in the world. The US Bureau of Census continued research on the development of seasonal adjustment methods and recently produced a beta version called X13-ARIMA-SEATS which enables the estimation of the seasonal component either via linear filters as those available in X12ARIMA or based on an ARIMA decomposition model.

All the moving average methods here discussed are nonlinear; hence, the seasonally adjusted total of aggregated series is not equal to the algebraic sum of the seasonally adjusted series that enter into the aggregation. The main causes of nonlinearity are: (1) a multiplicative decomposition model for the unobserved components, (2) the identification and replacement of extreme values, (3) the ARIMA extrapolations, and (4) automatic selection of moving average length for the estimation of the trend-cycle and seasonality.

The properties of the combined linear filters applied to estimate the various components were originally calculated by Young (1968) for a standard option. Later, Dagum et al. (1990) calculated and analyzed all possible filter combination of Census X11 and X11ARIMA. In the same context, Cleveland and Tiao (1976) and Burridge and Wallis (1984) found ARIMA models that approximated well some of the linear filters used for the trend-cycle and seasonal component of Census X11.

Model-Based Seasonal Adjustment Methods

The best known model-based methods are: (1) the regression methods with global or locally deterministic models for each component, and (2) stochastic model based methods that use ARIMA models.

Regression Methods

Seasonal adjustment by regression methods is based on the assumption that the systematic components of time series can be closely approximated by simple function of times over the *entire* span of the raw series. In general, two types of mathematical functions are considered. One is a polynomial of fairly low degree to represent the trend component; the other, linear combinations of sine and cosine functions with different periodicity and fixed amplitude and phase, to represent business cycles and seasonality. To overcome the limitation of using global deterministic representations for the trend, cycle, and seasonality, regression methods were extended to incorporate stochastic representations by means of local polynomials (spline functions) for successive short segments of the series and introducing changing seasonal amplitudes. A major breakthrough in this direction was made by Akaike (1980) who introduced prior constraints to the degree of smoothness of the various components and solved the problem with the introduction of a Bayesian model. Another important contribution is the regression method with locally deterministic models estimated by the LOESS (locally weighted regression) smoother developed by Cleveland et al. (1990).

The simplest and often studied seasonal adjustment regression method assumes that the generating process of seasonality can be represented by strictly periodic functions of time of annual periodicity. The problem is to estimate s seasonal coefficients (s being the seasonal periodicity, e.g., 12 for monthly series, 4 for quarterly series) subject to the seasonal constraint that they sum to zero.

This regression seasonal model can be written as

$$\begin{aligned} Y_t &= S_t + \varepsilon_t, \quad t = 1, \ldots, T; \\ S_t &= \sum_{j=1}^{s} \gamma_j d_{jt} \quad \text{subject to} \quad \sum_{j=1}^{s} \gamma_j = 0 \end{aligned} \qquad [2]$$

here the d_j's are dummy variables taking a value of unity in season j and a value of zero otherwise; $\{\varepsilon_t\} \sim \mathrm{WN}(0, \sigma_\varepsilon^2)$ is a white noise process with zero mean, homoscedastic, and nonautocorrelated. The seasonal parameters γ_js can be interpreted

as the expectation of Y_t in each season and represent the seasonal effects of the series under question. Since the parameters are constant, the seasonal pattern repeats exactly over the years, that is,

$$S_t = S_{t-s}, \text{ for all } t > s \quad [3]$$

Equation [2], often included in econometric models, assumes that the effects of the seasonal variations are deterministic because they can be predicted with no error. However, for most economic and social time series, seasonality is not deterministic but changes gradually in a stochastic manner. One representation of stochastic seasonality is to assume in regression eqn [2] that the γ_js are random variables instead of constant. Hence, the relationship, eqn [3], becomes

$$S_t = S_{t-s} + \omega_t, \text{ for all } t > s \quad [4]$$

where $\{\omega\} \sim \mathrm{WN}(0, \sigma_\omega^2)$ and $\mathrm{E}(\omega_t \varepsilon_t) = 0$, for all t. The stochastic seasonal balance constraint is here given by $\sum_{j=0}^{s-1} S_{t-j} = \omega_t$ with expected value equal to zero.

Equation [4] assumes seasonality to be generated by a nonstationary stochastic process. In fact, it is a random walk process and can be made stationary by seasonal differencing $\nabla_s = (1 - B^s)$ where B denotes the backward shift operator. In reduced form, the corresponding regression model is a linear combination of white noise processes of maximum lag s. Since $(1 - B^s) = (1 - B)(1 + B + \cdots + B^{s-1})$, model-based seasonal adjustment methods attribute only $S(B) = \sum_{j=0}^{s-1} B^j$ to the seasonal component leaving $(1 - B)$ as part of a nonstationary trend. Thus, the corresponding seasonal stochastic model can be written as

$$S(B)S_t = \omega_t, \quad [5]$$

Equation [6] represents a seasonality that evolves in an erratic manner and it was included in seasonal adjustment methods based on structural model decomposition (see, e.g., Harvey, 1981; Kitagawa and Gersch, 1984). This seasonal behavior is seldom found in observed time series where seasonality evolves smoothly through time. To represent this latter, Hillmer and Tiao (1982) introduced a major modification

$$S(B)S_t = \eta_s(B)b_t \quad [6]$$

where the left-hand side of eqn [6] follows an invertible moving average process of maximum order $s - 1$, denoted by MA($s - 1$). Equation [6] is discussed extensively in Bell and Hillmer (1984) and can be generalized easily by replacing the MA part with stationary invertible autoregressive moving average (ARMA) processes of the Box and Jenkins (1970) type. Depending on the order of the ARMA process a large variety of evolving stochastic seasonal variations can be modeled.

Other seasonal models used in regression methods where the components are assumed to be local polynomials of time, are based on a smoothness criterion. For example, given $Y_t = S_t + \varepsilon_t$, $t = 1, \ldots, T$, restrictions are imposed on S_t, such that, $\sum_t (S_t - S_{t-s})^2$ and $\sum_t [S(B)S_t]^2$ be small. The solution is given by minimizing a weighted linear combination of both criteria as follows

$$\sum_{t=1}^{T} (Y_t - S_t)^2 + \alpha \sum_{t=1}^{T} (S_t - S_{t-s})^2 + \beta \sum_{t=1}^{T} [S(B)S_t]^2 \quad [7]$$

where the ill-posed problem of choosing the α and β parameters was solved by Akaike (1980) using a Bayesian model.

Mixed seasonal models with deterministic and stochastic effects are given in Pierce (1978).

Stochastic Model Based Methods

Stochastic model based methods were mainly developed during the 1980 following two different approaches. One, originally known as seasonal adjustment by signal extraction (SIGEX) was developed by Burman (1980) and as ARIMA model based seasonal adjustment (Hillmer and Tiao, 1982) largely discussed in Bell and Hillmer (1984), the other is referred to as structural model decomposition method (see e.g., Harvey, 1981; Kitagawa and Gersch, 1984). The main difference between these two approaches is that in the latter simple ARIMA models are directly specified for each unobserved component whereas in the former an overall ARIMA model is obtained from observable data, and by imposing certain restrictions, models for each component are derived. Since the components are unknown, to obtain a unique decomposition Hillmer and Tiao (1982) proposed a canonical decomposition which has the properties, among others, of maximizing the variance of the irregulars and minimizing the variance of the stochastic seasonal models.

ARIMA models identification and estimation are sensitive to outliers or extreme values and cannot deal with deterministic components such as trading days and moving holidays. Therefore further developments were made by combining dummy variables regression models with ARIMA models to deal with these cases. In this regard, Gomez and Maravall (1996) developed at the Bank of Spain a seasonal adjustment software called TRAMO-SEATS which is currently applied mainly by European statistical agencies. TRAMO stands for "Time Series Regression with ARIMA noise, Missing observations and Outliers" and SEATS for "Signal Extraction in ARIMA Time Series." Firstly, TRAMO first estimates via regression dummy variables and direct ARIMA modeling, the deterministic components, which are removed from the input data. In a second round, SEATS estimates the seasonality and trend-cycle components from an ARIMA model fitted to the data where the deterministic components are removed. SEATS uses the filters derived from the linearized ARIMA model that describes the behavior of the time series. It should be mentioned that Eurostat, with the collaboration of the Bank of Belgium, the US Bureau of the Census, the Bank of Spain, and the European Central Bank, is developing an interface of TRAMO-SEATS and X12-ARIMA called DEMETRA+, entirely reprogrammed in "dot.com" following the "TRAMO-SEATS components" application developed at the National Bank of Belgium (DEMETRA+ will replace the old DEMETRA). At the Bank of Spain and Eurostat web site it is also possible to find a considerable number of papers relevant to TRAMO-SEATS as well as in the European Statistical System (ESS) Guidelines.

On the other hand the structural model decomposition method starts directly with an observation equation (sometimes called measurement equation) consisting of the unobserved components. Simple ARIMA or stochastic trigonometric models are assumed for each component. The structural model

is cast in a state-space form and estimated with Kalman filtering and smoothing. Koopman et al. (1998) developed STAMP that stands for Structural Time Series Analyser, Modeller and Predictor and includes several types of models for each component. STAMP is set up in an easy-to-use form which enables the user to concentrate on model selection and interpretation. STAMP 8 is an integrated part of the OxMetrics modular software system for time series data analysis, forecasting, financial econometric modeling, and the statistical analysis of cross-section and panel data. STAMP is not used officially by statistical agencies but mainly by econometricians, academics, and researchers involved with time series analysis, forecasting, financial econometric modeling, and statistical analysis of cross-section and panel data.

Conclusion

Seasonal adjustment plays a significant role in standardizing time series for the analysis of current social and economic conditions, particularly in determining the stages of the business cycle at which the economy stands. Such knowledge provides the bases for decision making to control the level of economic activity and it is of major importance around turning points.

The fact that seasonality and the other time series components, trend and cycle, change through time leads to major modifications of the traditional methods based on moving averages and to the development of new ones mainly based on ARIMA models.

After the 1990s, major financial, economic, and ecological changes of a global character have introduced more variability in time series and, consequently, in their seasonally adjusted values, making it very difficult to determine the direction of the short-term trend for an earlier detection of a turning point. As a consequence, producers and users of seasonally adjusted data have centered their attention on the need for further smoothing. In this regard, new research has been oriented toward a better estimation of the trend-cycle for current economic analysis, including parametric and non-parametric approaches as well as linear and nonlinear smoothers. For information on trend-cycle estimation the reader may refer to Kenny and Durbin (1982), Maravall (1993), Dagum (1996), Dagum and Luati (2009, 2012), Dagum and Bianconcini (2008, 2013), and references given therein. The presence of many outlying observations have also stimulated research on nonlinear and non-Gaussian models for seasonal adjustment. More information on seasonal adjustment theory and practice can be found in Hylleberg (1992), Zellner (1978, 1983), and Bell et al. (2012).

Abstract

State space modeling provides a unified methodology for treating a wide range of problems in time series analysis. The Kalman filter and its related methods have become key tools in the analysis of time series in economics, finance, and in many other fields as well. In an increasingly more complex world, static and dynamic models have proven to be too limited in empirical and relevant policy studies. The modeling of time-varying features in a time series has been given much attention recently. In this article we review and provide some adequate details and guidance for the adaptation of state space methods in univariate and multivariate time series analysis. We provide more detailed discussions for linear Gaussian model formulations and more concise reviews for nonlinear and non-Gaussian departures.

Introduction

State space methods originated in the field of control engineering, starting with the groundbreaking paper of Kalman (1960). They were initially (and still are) deployed for the purpose of accurately tracking the position and velocity of moving objects such as ships, airplanes, missiles, and rockets. Around the 1980s it was recognized in other fields than control engineering that these ideas could be applied to time series analysis generally as well. Since then state space methods have been applied in a wide range of subjects, including economics, finance, political science, environmental science, road safety, and medicine. The monographs of Harvey (1989) and West and Harrison (1997) have been instrumental in the dissemination of state space methods outside the field of control engineering.

Nowadays state space methods are widely used for a range of purposes and applications in the statistical analysis of time series. It has been recognized that many different models can be represented in state space form and be analyzed using the Kalman filter and related methods. The applications range from the fitting of autoregressive integrated moving average (ARIMA) models of Box and Jenkins (1976) when missing observations are present, to the forecasting of time series using high-dimensional time-varying parameter models as formulated by Watson and Engle (1983), and to the decomposition of time series into trend, seasonal, and irregular components using the structural time series model of Harvey (1989).

Linear Gaussian State Space Models

A time series is a set of observations which are sequentially ordered over time. In a state space analysis, the time series observations are assumed to depend linearly on a *state vector* that is unobserved and is generated by a stochastically time-varying process (a dynamic system). The observations are further assumed to be subject to measurement error that is independent of the state vector. The state vector can be estimated or identified once a sufficient set of observations become available. In this section we concentrate on the state space model and its special cases. In Section State Space Analysis we will discuss methods for estimation, residual analysis, and forecasting on the basis of state space models. The expositions below rely on the treatments provided by the introductory textbook of Commandeur and Koopman (2007), the introductory paper of Commandeur et al. (2011), and the more advanced textbooks of Harvey (1989) and Durbin and Koopman (2012).

The general linear Gaussian state space model for the n-dimensional observation sequence $y_1, \ldots, y_n$ can be written as

$$y_t = Z_t\alpha_t + \varepsilon_t, \quad \varepsilon_t \sim \mathrm{NID}(0, H_t) \qquad [1]$$

$$\alpha_{t+1} = T_t\alpha_t + R_t\eta_t, \quad \eta_t \sim \mathrm{NID}(0, Q_t), \quad t = 1, \ldots, n \qquad [2]$$

where α_t is the state vector; ε_t and η_t are disturbance vectors; and the system matrices Z_t, T_t, R_t, H_t, and Q_t are fixed and known but a selection of elements may depend on an unknown parameter vector. Equation [1] is called the *observation* or *measurement equation*, while eqn [2] is called the *state* or *transition equation*. The $p \times 1$ vector, y_t, represents p dependent variables for which we assume to have observations available for all time periods $t = 1, \ldots, n$. All methods reviewed below can treat the case where ranges of observations are missing for the p variables. The $m \times 1$ state vector, α_t, represents unobserved dynamic processes but may also contain fixed effects such as unknown constants and regression coefficients. The $p \times 1$ irregular vector, ε_t, has zero mean and $p \times p$ variance matrix H_t.

The $p \times m$ matrix, Z_t, links the observation vector, y_t, with the state vector, α_t, and may consist of regression variables. It is therefore necessary to assume that Z_t is time-varying but as a deterministic or exogenous process. The $m \times m$ transition matrix, T_t, in eqn [2] determines the dynamic evolution of the unobserved processes in the state vector. The $r \times 1$ disturbance vector, η_t, for the state vector update has zero mean and $r \times r$ variance matrix, Q_t. The observation and state disturbances, ε_t and η_t, are assumed to be serially independent and independent of each other at all time points. In many standard cases, $r = m$ and matrix R_t is the identity matrix I_m. In other cases, matrix R_t is an $m \times r$ selection matrix with $r < m$. Although matrix R_t can be specified freely, it is often composed of a selection from the first r columns of the identity matrix I_m.

The initial state vector α_1 is assumed to be generated as

$$\alpha_1 \sim \mathrm{NID}(a_1, P_1)$$

independently of the observation and state disturbances ε_t and η_t. Mean a_1 and variance P_1 can be treated as given and known in almost all stationary processes for the state vector. For nonstationary processes and regression effects in the state vector, the associated elements in the initial mean a_1 can be treated as unknown and need to be estimated. For an extensive discussion of *initialization* in state space analysis, we refer to Durbin and Koopman (2012: Chapter 5).

Local Level Model and Other Unobserved Component Models

By appropriate choices of the vectors α_t, ε_t, and η_t, and of the matrices Z_t, T_t, H_t, R_t, and Q_t, a wide range of different time series models can be derived from eqns [1] and [2]. Here we discuss the class of *unobserved components time series models*. A number of special cases will be discussed in some detail. Special attention is given to the univariate *local level model*.

By having

$$\alpha_t = \mu_t, \quad \eta_t = \xi_t, \quad Z_t = T_t = R_t = 1, \quad H_t = \sigma_\varepsilon^2, \quad Q_t = \sigma_\xi^2$$

(all of order 1×1) for $t = 1, \ldots, n$, models [1] and [2] reduce to the local level model as given by

$$\begin{aligned} y_t &= \mu_t + \varepsilon_t, \quad \varepsilon_t \sim \mathrm{NID}\left(0, \sigma_\varepsilon^2\right) \\ \mu_{t+1} &= \mu_t + \xi_t, \quad \xi_t \sim \mathrm{NID}\left(0, \sigma_\xi^2\right) \end{aligned} \qquad [3]$$

for $t = 1, \ldots, n$. The level component, μ_t, can be regarded as the time-varying equivalent of the intercept in the classical linear regression model $y_t = \mu + \varepsilon_t$ which is obtained by setting all the level disturbances ξ_t in eqn [3] equal to zero and with $\mu = \mu_1$. The key difference is that the intercept μ in a regression model is fixed whereas the level component, μ_t, in eqn [3] is allowed to change from time point to time point.

Since the second equation in eqn [3] defines a random walk, the local level model is also referred to as the random walk plus noise model (where the noise refers to the irregular component ε_t). It can be shown that the dynamic process for $x_t = y_{t+1} - y_t = \eta_t + \varepsilon_{t+1} - \varepsilon_t$, when $t = 1, \ldots, n$, reduces to the moving average process $x_t = \varepsilon_t + \theta\varepsilon_{t-1}$ where θ relates to the *signal-to-noise ratio* $q = \sigma_\xi^2/\sigma_\varepsilon^2$ via a quadratic function. A key notion is that the moving average coefficient, θ, in the x_t process is restricted to $-0.5 < \theta < 0$ for $q > 0$. Furthermore, the forecasting function of the local level model eqn [3] is equivalent to the *exponentially weighted moving average* (or *exponential smoothing*) scheme where the smoothing coefficient is directly related to q as well.

By having

$$\alpha_t = \begin{pmatrix} \mu_t \\ \nu_t \end{pmatrix}, \quad \eta_t = \begin{pmatrix} \xi_t \\ \zeta_t \end{pmatrix}, \quad T_t = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}, \quad Z_t = (1 \quad 0),$$

$$H_t = \sigma_\varepsilon^2, \quad Q_t = \begin{bmatrix} \sigma_\xi^2 & 0 \\ 0 & \sigma_\zeta^2 \end{bmatrix}, \text{ and } R_t = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$$

and by representing the resulting eqns [1] and [2] in scalar form, we obtain the local linear trend model as given by

$$\begin{aligned} y_t &= \mu_t + \varepsilon_t, & \varepsilon_t &\sim \mathrm{NID}\left(0, \sigma_\varepsilon^2\right) \\ \mu_{t+1} &= \mu_t + \nu_t + \xi_t, & \xi_t &\sim \mathrm{NID}\left(0, \sigma_\xi^2\right) \\ \nu_{t+1} &= \nu_t + \zeta_t, & \zeta_t &\sim \mathrm{NID}\left(0, \sigma_\zeta^2\right) \end{aligned} \qquad [4]$$

for $t = 1, \ldots, n$.

The local linear trend model requires a 2×1 state vector α_t: one element for the level component, μ_t, and one element for the slope component, ν_t. The slope or gradient component represents the linear growth of the trend component. It can be conceived of as the time-varying equivalent of the regression coefficient in the classical regression model where the observed time series y_t is regressed on the 'exogenous variable' time index t: $y_t = \mu + \nu t + \varepsilon_t$ with $\mu = \mu_1$ and $\nu = \nu_1$. The key difference of the models is that the regression coefficient or weight ν is fixed in the classical linear regression model, whereas the slope ν_t in the local linear trend model is allowed to stochastically change over time.

In situations where the observed time series consists of quarterly or monthly data, for example, the local level and the local linear trend model can be extended with a stochastically evolving seasonal dummy component denoted here by γ_t. In the case of a quarterly time series (the seasonal length s equals 4), by having

$$\alpha_t = \begin{pmatrix} \mu_t \\ \gamma_{1,t} \\ \gamma_{2,t} \\ \gamma_{3,t} \end{pmatrix}, \quad \eta_t = \begin{pmatrix} \xi_t \\ \omega_t \end{pmatrix},$$

$$T_t = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & -1 & -1 & -1 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \end{bmatrix}, \quad Z_t = (1 \quad 1 \quad 0 \quad 0),$$

$$H_t = \sigma_\varepsilon^2, \quad Q_t = \begin{bmatrix} \sigma_\xi^2 & 0 & 0 & 0 \\ 0 & \sigma_\omega^2 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}, \text{ and } R_t = \begin{bmatrix} 1 & 0 \\ 0 & 1 \\ 0 & 0 \\ 0 & 0 \end{bmatrix}$$

and by formulating eqns [1] and [2] in scalar notation, we obtain

$$\begin{aligned} y_t &= \mu_t + \gamma_{1,t} + \varepsilon_t, & \varepsilon_t &\sim \mathrm{NID}\left(0, \sigma_\varepsilon^2\right) \\ \mu_{t+1} &= \mu_t + \xi_t, & \xi_t &\sim \mathrm{NID}\left(0, \sigma_\xi^2\right) \\ \gamma_{1,t+1} &= -\gamma_{1,t} - \gamma_{2,t} - \gamma_{3,t} + \omega_t, & \omega_t &\sim \mathrm{NID}\left(0, \sigma_\omega^2\right) \end{aligned} \qquad [5]$$

with $\gamma_{2,t+1} = \gamma_{1,t}$ and $\gamma_{3,t+1} = \gamma_{2,t}$, for $t = 1, \ldots, n$. It is the formulation of a level plus seasonal model for a quarterly time series with stochastically time-varying level and seasonal components. The seasonal dummy model is not the only specification for incorporating a time-varying seasonal effect in an unobserved components time series model; see Proietti (2000) for a review of different seasonal models and their properties. When the slope component, ν_t, is included in the level component, μ_t, in eqn [5] as well, we obtain the *basic structural time series model* of Harvey (1989). A typical application of this model is for the *seasonal adjustment* of time series. A seasonally adjusted time series is defined in this context simply by the estimate of $y_t - \gamma_t = \mu_t + \varepsilon_t$ for $t = 1, \ldots, n$.

Another and final extension is to include one or more cycles to any of the unobserved components time series models as formulated above. For example, by having

$$\alpha_t = \begin{pmatrix} \mu_t \\ c_t \\ c_t^* \end{pmatrix}, \quad \eta_t = \begin{pmatrix} \xi_t \\ \kappa_t \\ \kappa_t^* \end{pmatrix},$$

$$T_t = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \rho\cos(\lambda_c) & \rho\sin(\lambda_c) \\ 0 & -\rho\sin(\lambda_c) & \rho\cos(\lambda_c) \end{bmatrix}, \quad Z_t = (1 \quad 1 \quad 0),$$

$$H_t = \sigma_\varepsilon^2, \quad Q_t = \begin{bmatrix} \sigma_\xi^2 & 0 & 0 \\ 0 & \sigma_c^2(1-\rho^2) & 0 \\ 0 & 0 & \sigma_c^2(1-\rho^2) \end{bmatrix},$$

$$\text{and } R_t = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

in eqns [1] and [2], we obtain the level plus cycle model as given by

$$\begin{aligned} y_t &= \mu_t + c_t + \varepsilon_t, \\ \mu_{t+1} &= \mu_t + \xi_t, \\ c_{t+1} &= \rho\left[\cos(\lambda_c)c_t + \sin(\lambda_c)c_t^*\right] + \kappa_t, \\ c_{t+1}^* &= \rho\left[-\sin(\lambda_c)c_t + \cos(\lambda_c)c_t^*\right] + \kappa_t^*, \\ \xi_t &\sim \mathrm{NID}\left(0, \sigma_\xi^2\right) \\ \xi_t &\sim \mathrm{NID}\left(0, \sigma_\xi^2\right) \\ \kappa_t &\sim \mathrm{NID}\left[0, \sigma_c^2(1-\rho^2)\right] \\ \kappa_t^* &\sim \mathrm{NID}\left[0, \sigma_c^2(1-\rho^2)\right] \end{aligned} \qquad [6]$$

for $t = 1, \ldots, n$, where $0 < \rho \leq 1$ is the *damping factor* and λ_c is the frequency of the cycle measured in radians so that $2\pi/\lambda_c$ is the overall *period* of the cycle. In case $\rho = 1$, the cycle reduces to a fixed sine–cosine wave but the component is still stochastic since the initial values c_1 and c_1^* are stochastic variables with mean zero and variance σ_c^2. A typical application of this model is for the signal extraction of *business cycles* from economic time series.

Regression and Intervention Effects

Time series variables can be subject to specific effects and events that occur within a time period. We can capture these by including fixed explanatory and intervention variables in the model. The explanatory variable typically varies for each time period, while the intervention variable is designed to capture a specific effect in the dependent variable such as an outlier due to an extreme event or a structural break due to a policy or regime change. The intervention variable represents an outlier when all values are zero except at one time point where it equals unity. It represents a structural break when all values are zero up to a time point and all values are unity after this time point. Other types of intervention effects can also be specified; see Box and Tiao (1975).

Suppose a single regression variable, x_t, and a specific intervention variable, w_t, need to be included in the local level model, we have $y_t = \mu_t + \beta x_t + \lambda w_t + \varepsilon_t$, for $t = 1, \ldots, n$, as our model of interest, where β and λ are fixed unknown regression coefficients. The state space model representation of this model requires a state vector of three elements: one for the level component μ_t, one for the regression coefficient β, and one for the intervention coefficient λ. The substitution of

$$\alpha_t = \begin{pmatrix} \mu_t \\ \beta_t \\ \lambda_t \end{pmatrix}, \quad \eta_t = \xi_t, \quad T_t = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}, \quad Z_t = (1 \quad x_t \quad w_t),$$

$$H_t = \sigma_\varepsilon^2, \quad Q_t = \begin{bmatrix} \sigma_\xi^2 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \text{ and } R_t = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}$$

in eqns [1] and [2] leads to

$$\begin{aligned} y_t &= \mu_t + \beta_t x_t + \lambda_t w_t + \varepsilon_t, & \varepsilon_t &\sim \mathrm{NID}\left(0, \sigma_\varepsilon^2\right) \\ \mu_{t+1} &= \mu_t + \xi_t, & \xi_t &\sim \mathrm{NID}\left(0, \sigma_\xi^2\right) \end{aligned}$$

for $t = 1, \ldots, n$, with $\beta_{t+1} = \beta_t = \beta_1 = \beta$ and $\lambda_{t+1} = \lambda_t = \lambda_1 = \lambda$. This is the local level model with an explanatory variable x_t and an intervention variable w_t. By adding disturbance terms to the state vector element with β_t, the regression coefficient effectively becomes a random walk process. Hence, this specification allows easily for the estimation of time-varying regression effects; see Harrison and Stevens (1976) for an early application.

Structural Time Series Analysis

From the previous sections, a structural approach to time series analysis emerges which is facilitated by the state space framework. In this approach, different unobserved components or building blocks responsible for the dynamics of the series such as trend, seasonal, cycle, and the effects of explanatory and intervention variables are identified separately before being put together in a state space model. It is the responsibility of the researcher to decide what components are required in a specific situation, and then to consider whether they apply to the time series under consideration. This explains why state space models are often referred to as *structural time series models*.

ARIMA and ARIMA Components Models

A more traditional approach to time series analysis is proposed in Box and Jenkins (1976); see also the discussions in Tiao (2014). We show how the *ARIMA* model can be put into state space form. An essential feature of the Box–Jenkins approach to time series analysis is that the observed time series is assumed to be *stationary*, meaning that its means and covariances should be invariant when the series is shifted or translated through time. If an observed time series is stationary, then its analysis can be based on an *autoregressive moving average* (ARMA) model. However, if nonstationary features are present, the Box–Jenkins analysis suggests to enforce stationarity by *differencing* the time series. The key features of the series such as trend and seasonal will be removed from the series y_t by transforming it into

$$\Delta y_t = y_t - y_{t-1}$$

to remove the trend from the series, and

$$\Delta_s y_t = y_t - y_{t-s}$$

to remove the seasonal effect with periodicity s from the series.

To illustrate how an ARMA model can be formulated in state space form, we consider the ARMA(2, 1) model

$$y_t = \phi_1 y_{t-1} + \phi_2 y_{t-2} + \zeta_t + \theta_1 \zeta_{t-1}, \quad \zeta_t \sim \mathrm{NID}\left(0, \sigma_\zeta^2\right)$$

for $t = 1, \ldots, n$, where we assume that the observed series already satisfies stationarity; see Tiao (2014) for further details. By considering the state space models [1] and [2], and by defining

$$\alpha_t = \begin{pmatrix} y_{t+1} \\ \phi_2 y_t + \theta_1 \zeta_{t+1} \end{pmatrix}, \quad \eta_t = \zeta_{t+1}, \quad T_t = \begin{bmatrix} \phi_1 & 1 \\ \phi_2 & 0 \end{bmatrix},$$

$$Z_t = (1 \quad 0), \quad H_t = 0, \quad Q_t = \sigma_\zeta^2, \text{ and } R_t = \begin{bmatrix} 1 \\ \theta_1 \end{bmatrix}$$

for $t = 1, \ldots, n$, we have represented the ARMA(2, 1) model in the state space framework. For a general overview of how any of the ARIMA(p, d, q) models can be represented in the state space framework, we refer to Durbin and Koopman (2012: Section 3.4).

A more general approach to time series analysis can be based on the ARIMA components model as given by

$$y_t = \sum_{j=1}^{m} \mu_t^{(j)}, \quad \mu_t^{(j)} \sim \mathrm{ARIMA}, \quad j = 1, \ldots, m \qquad [7]$$

for $t = 1, \ldots, n$, where the $\mu_t^{(j)}$'s follow mutually independent ARIMA processes with different levels of differencing and different values for p and q for $j = 1, \ldots, m$. The dynamic properties of y_t can be derived from the different ARIMA processes, while the time series y_t can be expressed as an ARIMA process itself. Unobserved components time series models can be regarded as special cases of the ARIMA components model. For example, the local level model [3] can be expressed as an ARIMA components model with $m = 2$, $\mu_t^{(1)} = \mu_t$, and $\mu_t^{(2)} = \varepsilon_t$. We take $\mu_t^{(1)}$ as an ARMA(0, 0) process after first differencing (with $p = 0$ and $q = 0$), and we take $\mu_t^{(2)}$ as an ARMA(0, 0) process without differencing. A more general and more detailed discussion of ARIMA components models can be found in Bell (2004).

Multivariate Models

The structural approach to time series analysis is easily extended to multivariate time series. For example, when we denote y_t as a $p \times 1$ vector of observations, a multivariate local level model can be adopted for modeling the p time series simultaneously:

$$\begin{aligned} y_t &= \mu_t + \varepsilon_t, \quad \varepsilon_t \sim \mathrm{NID}(0, \Sigma_\varepsilon) \\ \mu_{t+1} &= \mu_t + \xi_t, \quad \xi_t \sim \mathrm{NID}(0, \Sigma_\xi) \end{aligned} \qquad [8]$$

for $t = 1, \ldots, n$, where μ_t, ε_t, and ξ_t are $p \times 1$ vectors and Σ_ε and Σ_ξ are $p \times p$ variance matrices. In what is known as the *seemingly unrelated time series equations model* [8], the series are modeled as in the univariate situation, but the disturbances driving the level components are allowed to be instantaneously correlated across the p series. When slope, seasonal, or cycle components are also included in the model, each of these three components has an associated $p \times p$ variance matrix for their disturbance vectors, allowing for correlation between the series.

If the rank r of Σ_ξ in eqn [8] is assumed smaller than p, then the model implies that the p series have r *common levels*. Such common factors may not only have a nice and interesting interpretation, but may also result in more efficient inferences and forecasts since the number of parameters reduces.

The Latent Risk Model

Risk is at the center of many policy decisions in many kinds of organizations. In risk analysis, measures of exposure to risk, outcomes (or events), and, possibly, losses are analyzed. Risk itself is not observed. For example, in case of road safety research, exposure is the number of cars (or the number of kilometers traveled), outcome is the number of accidents, and loss is the cost of damages (or the number of fatalities). From these measures we can learn about risk and its associated severity. In a time series context, we typically observe the measures in totals for a country (or a region, or a specific group) and for a specific period (month, quarter, or other). The time series for exposure y_{1t}, outcome y_{2t}, and loss y_{3t} are typically observed with error and are subject to, possibly, trend, seasonal, cycle, and regression effects. We can carry out a time series analysis with directly interpretable variables via the multiplicative latent risk model

$$y_{1t} = \mu_{1t} \times \xi_{1t}, \quad y_{2t} = \mu_{1t} \times \mu_{2t} \times \xi_{2t},$$

$$y_{3t} = \mu_{1t} \times \mu_{2t} \times \mu_{3t} \times \xi_{3t}$$

where μ_{1t} is exposure corrected for observation error, μ_{2t} is risk, and μ_{3t} is severity, while ξ_{jt} are the multiplicative errors with their means equal to 1, for $j = 1, 2, 3$. The model implies that expected outcome is the product of exposure and risk, while expected loss is the product of outcome and severity. By taking logs we obtain the trivariate latent risk model in additive form

$$\begin{pmatrix} \log y_{1t} \\ \log y_{2t} \\ \log y_{3t} \end{pmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 1 & 1 & 0 \\ 1 & 1 & 1 \end{bmatrix} \theta_t + \varepsilon_t$$

with the signal vector $\theta_t = (\log \mu_{1t}, \log \mu_{2t}, \log \mu_{3t})'$ and with the disturbance vector $\varepsilon_t = (\log \xi_{1t}, \log \xi_{2t}, \log \xi_{3t})'$. The signals for exposure, risk, and severity (all three variables in logs) can be modeled simultaneously as linear functions of the state vector. Letting

$$\theta_t = S_t \alpha_t, \quad t = 1, \ldots, n$$

denote the signal vector where S_t is a $3 \times m$ system matrix that relates the signal θ_t with the state vector α_t, the model is placed in state space form [1] and [2] with

$$Z_t = \begin{bmatrix} 1 & 0 & 0 \\ 1 & 1 & 0 \\ 1 & 1 & 1 \end{bmatrix} S_t$$

Multiple measures for exposure, outcome, and/or loss can be incorporated in this framework in a straightforward manner. Typical applications for the latent risk model are for studies on insurance claims, credit card purchases, and road safety. Bijleveld et al. (2008) provide further discussions on the latent risk model and show how the general methodology can be effectively used in the assessment of risk.

Dynamic Factor Models

Principal components and factor analysis are widely used statistical methods in the applied social and behavioral sciences. These methods aim to identify commonalities in the covariance structure of high-dimensional data sets. A factor analysis model can be based on the form given by Lawley and Maxwell (1971), that is

$$y_i = \Lambda f_i + u_i, \quad f_i \sim N(0, \Sigma_f), \quad u_i \sim N(0, \Sigma_u)$$

where y_i represents a zero-mean data vector containing measured characteristics of subject i, for $i = 1, \ldots, n$, while Λ is the coefficient matrix for the low-dimensional vector f_j of latent variables. The latent vector f_i with its variance matrix Σ_f and the disturbance vector u_j with its variance matrix Σ_u are assumed to be mutually and serially independent for $i, j = 1, \ldots, n$. The factor analysis model implies the decomposition of the variance matrix of y_i into

$$\Sigma_y = \Lambda \Sigma_f \Lambda' + \Sigma_u$$

Estimation of Λ, Σ_f, and Σ_u can be carried out by maximum likelihood procedures; the loading coefficients in Λ and the variance matrices are subject to a set of linear restrictions necessary for identification. A detailed discussion of the maximum likelihood approach to factor analysis is given by Lawley and Maxwell (1971). In the application of factor analysis in a time series context, the measurements in y_i correspond to a time period t rather than a subject i, we therefore have y_t instead of y_i. The time dependence of the measurements can be accounted for by replacing the serially independence assumption for f_t by a serial dependence assumption. For example, we can assume that f_t is modeled by a vector autoregressive process. We can also let f_t depend on the state vector α_t in a linear way, that is, $f_t = U_t \alpha_t$ where U_t is typically a known selection matrix.

In applications to economics, y_t may consist of a large set of macroeconomic indicators associated with variables such as income, consumption, investment, and unemployment. These variables are all subject to economic activity that can often be related to the business cycle. The dynamic features of the business cycle may be disentangled into a set of factors with possibly different dynamic characteristics. In the context of finance, y_t may consist of a large set of daily prices or returns from individual stocks that make up the indices such as Standard & Poor's 500 and Dow Jones. A set of underlying factors may represent returns from particular portfolio strategies. In the context of marketing, y_t may contain market shares of groups or subgroups of product brands. The factors may indicate whether marketing strategies in certain periods affect all market shares or only a selection of market shares. In all these cases it is not realistic to assume that the factors are independent over time so we require to formulate a dynamic process for the factors. The wide variety of applications of factor analysis in a time series context have led to many contributions in the statistics and econometrics literature on the inference of dynamic factor models; see, for example, Geweke (1977), Engle and Watson (1981), Watson and Engle (1983), Litterman and Scheinkman (1991), Quah and Sargent (1993), Stock and Watson (2002), Doz et al. (2006), and Diebold et al. (2006).

The dynamic factor model can be regarded as a state space model in which the state vector consists of latent factors where dynamic properties are formulated in the state equation of the state space models [1] and [2]. The size of the observation vector is typically large, while the dimension of the state vector is small so we have $p \gg m$. In the example

$$y_t = \Lambda f_t + \varepsilon_t, \quad f_t = U_t \alpha_t, \quad \varepsilon_t \sim N(0, H_t)$$

the dynamic factor model is a special case of the state space models [1] and [2] for which the observation equation has $Z_t = \Lambda U_t$.

State Space Analysis

For given values of all system matrices – and for given initial conditions a_1 and P_1 – the state vector can be estimated in three different ways, yielding what are known as the *filtered*, the *predicted*, and the *smoothed* estimates of the state vector. Depending on the types of state estimates required in the analysis, the estimates of the state vector can be obtained by performing one or two passes through the observed time series:

1. a *forward* pass, from $t = 1, \ldots, n$, using a recursive algorithm known as the *Kalman filter* enables the computation of predicted states, based on $y_1, \ldots, y_{t-1}$; filtered states, based on $y_1, \ldots, y_t$; and observation prediction errors;
2. a *backward* pass, from $t = n, \ldots, 1$, using output of the Kalman filter and using recursive algorithms known as *state and disturbance smoothers* enable the computation of smoothed estimates of states and disturbances that are based on all observations $y_1, \ldots, y_n$.

Kalman Filter for Prediction, Filtering, and Forecasting

The forward pass through the data with the well-known Kalman (1960) filter provides all estimates that are relevant for the filtered and the predicted state. The main purpose of the Kalman filter is to obtain optimal estimates of the state at time point t, *only* considering the observations $\{y_1, y_2, \ldots, y_{t-1}\}$. A key property of the predicted state and its related estimates is therefore that they are only based on *past values* of the observed time series. The recursive formulas for the Kalman filter are

$$\begin{aligned} v_t &= y_t - Z_t a_t, & F_t &= Z_t P_t Z_t' + H_t \\ K_t &= T_t P_t Z_t' F_t^{-1}, & L_t &= T_t - K_t Z_t \\ a_{t+1} &= T_t a_t + K_t v_t, & P_{t+1} &= T_t P_t L_t' + R_t Q_t R_t' \end{aligned} \qquad [9]$$

for $t = 1, \ldots, n$. The values of a_t in eqn [9] represent the predicted state, while the values of P_t quantify the estimation error variance matrix of the predicted state a_t. Under the assumption of normality, the latter variances are useful for the construction of *confidence intervals* for the predicted state, which – assuming that we are interested in their 90% confidence limits, for example – can be calculated as

$$a_t \pm 1.64\sqrt{P_t}$$

for $t = 1, \ldots, n$. A modification of the Kalman filter also allows the computation of the filtered estimate of the state vectors, that is

$$a_{t|t} = a_t + P_t Z_t' F_t^{-1} v_t, \quad P_{t|t} = P_t - P_t Z_t' F_t^{-1} Z_t P_t,$$
$$t = 1, \ldots, n$$

where $a_{t|t}$ is the optimal estimate of the state at time point t by considering the observations $\{y_1, y_2, \ldots, y_t\}$, while $P_{t|t}$ is the state-filtered estimation error variance matrix. The values of v_t in eqn [9] are called the *one-step ahead prediction* or *forecast* errors, since they quantify the lack of accuracy of a_t in predicting the observed value of y_t at time point t; the values of F_t are the variances of these one-step ahead prediction errors v_t.

One of the convenient features of state space methods is the ease with which they deal with two important aspects of time series analysis – forecasting and missing observations: by treating them in exactly the same way. Missing observations are handled by setting K_t and v_t in eqn [9] equal to zero. Forecasts for $y_{n+1}, \ldots, y_{n+k}$ given $y_1, \ldots, y_n$ are simply obtained by applying the Kalman filter for $t = 1, \ldots, n, n+1, \ldots, n+k$ and by treating $y_{n+1}, \ldots, y_{n+k}$ as missing observations.

State and Disturbance Smoothing

The backward pass through the data is only required for smoothing that leads to estimates such as the smoothed states and smoothed disturbances. The main purpose of state and disturbance smoothing is to obtain estimated values of the state and disturbance vectors at time point t, considering *all* available observations $\{y_1, y_2, \ldots, y_n\}$. The recursive formulas for state smoothing are

$$r_{t-1} = Z_t' F_t^{-1} v_t + Z_t' r_t, \quad N_{t-1} = Z_t' F_t^{-1} Z_t + L_t' N_t L_t \qquad [10]$$

$$\widehat{\alpha}_t = a_t + P_t r_{t-1}, \quad V_t = P_t - P_t N_{t-1} P_t \qquad [11]$$

for $t = n, \ldots, 1$. The recursive formulas for smoothing in eqn [10] are initialized with $r_n = 0$ and $N_n = 0$. The state smoothing eqn [11] yields the smoothed state estimate $\widehat{\alpha}_t$ and is defined as the optimal estimate of α_t using the full set of observations $\{y_1, y_2, \ldots, y_n\}$; the state smoothing equations also yield the corresponding smoothed state estimation error variance matrix V_t.

Analogous to the predicted state, under the assumption of normality the smoothed state estimation error variance matrix V_t is useful for the construction of confidence intervals for the smoothed state components, which – should we happen to be interested in their 90% confidence limits for example – can be calculated as

$$\widehat{\alpha}_t \pm 1.64\sqrt{V_t}$$

for $t = 1, \ldots, n$.

The recursions for r_{t-1} and N_{t-1} in eqn [10] also enable the computation of the smoothed estimates of the disturbances ε_t and η_t in the following way:

$$\widehat{\varepsilon}_t = H_t\left(F_t^{-1} v_t - K_t' r_t\right), \quad \mathrm{Var}(\widehat{\varepsilon}_t) = H_t\left(F_t^{-1} + K_t' N_t K_t\right) H_t \qquad [12]$$

$$\widehat{\eta}_t = Q_t R_t' r_t, \quad \mathrm{Var}(\widehat{\eta}_t) = Q_t R_t' N_t R_t Q_t \qquad [13]$$

for $t = n, \ldots, 1$. The eqns [12] and [13] compute the smoothed observation disturbances $\widehat{\varepsilon}_t$, the smoothed state disturbances $\widehat{\eta}_t$, and their corresponding smoothed estimation error variance matrices $\mathrm{Var}(\widehat{\varepsilon}_t)$ and $\mathrm{Var}(\widehat{\eta}_t)$, respectively.

Diagnostic Checking

All significance tests in linear Gaussian state space models and the construction of confidence intervals are based on three assumptions concerning the residuals of the analysis: the residuals should satisfy independence, homoscedasticity, and normality, in this order of importance. Whether the residuals satisfy these three assumptions can be established by diagnosing what are known as the *standardized prediction errors*. They are defined as

$$v_t^* = \frac{v_t}{\sqrt{F_t}} \qquad [14]$$

for $t = 1, \ldots, n$. For the computations of the one-step ahead prediction errors v_t and their variances F_t in eqn [14], we refer to the recursive formulas for the Kalman filter given in eqn [9]. In case y_t is a vector of time series, the prediction error v_t^* is defined by $v_t^* = G_t v_t$, where G_t is constructed such that $G_t G_t' = F_t^{-1}$.

The assumptions of independence and normality of the residuals can be diagnosed using the Box–Ljung test statistic and the Bowman and Shenton test statistic, respectively. The assumption of homoscedasticity can be checked by testing whether the variance of the standardized prediction errors in the first third part of the series is equal to the variance of the errors corresponding to the last third part of the series. For further details concerning these diagnostic tests, we refer to Harvey (1989), Durbin and Koopman (2012), and Commandeur and Koopman (2007).

A second diagnostic tool for determining the appropriateness of a model is provided by inspection of what are known as the *auxiliary residuals*. As already mentioned above, the disturbance smoothing filters applied in the backward pass through the data yield, among others, estimates of the smoothed observation and state disturbances, and of their variances. The auxiliary residuals are obtained by dividing the smoothed observation and state disturbances with the square root of their corresponding variances, as follows:

$$e_t^* = \frac{\widehat{\varepsilon}_t}{\sqrt{\mathrm{Var}(\widehat{\varepsilon}_t)}} \text{ and } r_t^* = \frac{\widehat{\eta}_t}{\sqrt{\mathrm{Var}(\widehat{\eta}_t)}} \qquad [15]$$

for $t = 1, \ldots, n$, resulting in *standardized* smoothed disturbances. Visual inspection of the standardized smoothed observation disturbances, e_t^*, allows for the detection of possible *outlier* observations in a time series, while inspection of the standardized smoothed state disturbances, r_t^*, enables the detection of *structural breaks* in the underlying development of a time series.

Each auxiliary residuals can be considered as a t-test for the null hypothesis that there was no outlier observation (when inspecting the auxiliary residuals at the left of eqn [15]) or as a t-test for the null hypothesis that there was no structural break in the corresponding unobserved component of the observed time series (when inspecting the auxiliary residuals at the right of eqn [15]). Applying the usual 95% confidence limits of ± 1.96 corresponding to a two-tailed t-test, possible outlier observations or structural breaks in the unobserved components making up the state vector are thus easily detected. A more detailed discussion on outlier and break detection in a state space analysis is provided by Harvey and Koopman (1992) and de Jong and Penzer (1998).

Parameter Estimation

So far, we have presented all of the results that can be obtained with state space methods as if the disturbance variances, the fixed regression effects, the parameters ρ and λ_c associated with cycles, etc., are given and known. In practice, of course, these parameters are unknown, and have to be estimated.

It can be shown that the Kalman filter presented in eqn [9] also provides the necessary ingredients required for evaluating the log-likelihood function, which is given by

$$\log L(y|\psi) = -\frac{np}{2}\log(2\pi) - \frac{1}{2}\sum_{t=1}^{n}\left(\log\left|F_t\right| + v_t' F_t^{-1} v_t\right) \quad [16]$$

where the v_t are the one-step ahead prediction errors, the F_t are their variances for $t = 1, \ldots, n$ defined in eqn [9], and ψ denotes the vector of unknown parameters. The log-likelihood eqn [16] is maximized with respect to ψ numerically using the score vector or the EM algorithm; see Durbin and Koopman (2012) and Commandeur and Koopman (2007) for details. In this way we obtain the maximum likelihood estimate of ψ.

Computing

State space methods have been implemented on many computer platforms and in many software packages including STAMP, R, MATLAB, REGCMPNT, SAS, EViews, GAUSS, Stata, RATS, gretl, and SsfPack with links established to S-PLUS and Ox. For more details and an overview of all these software packages, including many interesting applications to time series analysis, we refer to Commandeur et al. (2011).

Non-Gaussian and Nonlinear Time Series

The state space model eqns [1] and [2] are for Gaussian observations y_t that are modeled as linear functions of the state vector. In case of observations y_t that are discrete, are nonlinear in the state vector, or have other distributional properties than Gaussian, we can consider the generalized state space model

$$y_t \sim p(y_t|Z_t\alpha_t) \quad [17]$$

for $t = 1, \ldots, n$, where $p(\cdot)$ is a particular non-Gaussian density function, possibly for discrete observations, and with the state vector α_t and system matrix Z_t as defined in the previous section. The observation density $p(\cdot)$ may be Gaussian but implies a nonlinear relation with α_t. Conditional on the state vector α_t, we assume that the observations are serially independent. This assumption is similar to the linear Gaussian model where ε_t is assumed to be serially uncorrelated. In all cases, the state vector α_t evolves stochastically over time according to the linear Gaussian state eqn [2]. This condition may also be relaxed but in economics and finance we can mostly assume a linear Gaussian process for α_t.

Time series observations which come from the exponential family distribution require density function

$$p(y_t|\theta_t) = \exp\left[y_t'\theta_t - b_t(\theta_t) + c_t(y_t)\right] \quad [18]$$

where $\theta_t = Z_t\alpha_t$, $b_t(\cdot)$ is a twice differentiable function and $c_t(\cdot)$ is a function of y_t only. The modeling framework [17, 2, 18] makes it possible to analyze time series observations coming from, among others, Poisson, binary, binomial, and multinomial distributions. For example, in case a Poisson density is considered, we have $b_t(\theta_t) = \exp\theta_t$ and $c_t(y_t) = \log(y_t!)$.

The generalized state space models [17, 2, 18] are more general than the exponential family only. We can consider continuous density functions for $p(\cdot)$ such as those related to the heavy-tailed distributions Student's t, mixture of normals, and general error. In these cases, we can often return to the linear observation eqn [17] but written as

$$y_t = \theta_t + \varepsilon_t, \quad \varepsilon_t \sim p(\varepsilon_t)$$

where $p(\varepsilon_t) = p(y_t|\theta_t)$. When we take $p(\cdot)$ as the Gaussian density with mean zero and variance H_t, the generalized model reduces to the Gaussian state space models [1] and [2].

A particular example of a non-Gaussian model of interest for financial markets is the stochastic volatility model where the observations are financial returns with a constant mean and a stochastically time-varying variance. The univariate stochastic volatility model is given by

$$y_t = \exp\left(\frac{1}{2}\theta_t\right)\varepsilon_t, \quad \varepsilon_t \sim p(\varepsilon_t) \quad [19]$$

where $p(\varepsilon_t)$ can be Gaussian, Student's t, or mixture of normals. The log variance θ_t can be generally specified as $\theta_t = Z_t\alpha_t$ but it is usually considered as a stationary autoregressive process. For more detailed discussions concerning the stochastic volatility model [19], see Harvey et al. (1994) and Shephard (2005).

The statistical analysis based on nonlinear and non-Gaussian extensions of the state space model can still rely on linear methods such as the Kalman filter and smoothing recursions of Section State Space Analysis but the results may be highly inaccurate. A number of statistical approaches can be adopted to treat non-Gaussian and nonlinear features of the model more adequately and more accurately. For example, Durbin and Koopman (2000) have developed an estimation methodology based on importance sampling and simulated maximum likelihood methods. Bayesian estimation methods for the more general classes of state space models rely typically on Markov chain Monte Carlo methods which are originally developed by Frühwirth-Schnatter (1994), Carter and Kohn (1994), Shephard and Pitt (1997), and others.

Recent Developments

More recent developments on the analysis of generalized or nonlinear state space models are reported in the engineering literature. These developments are based on methods collectively known as particle filtering and originate from the work by Gordon et al. (1993), Kitagawa (1996), and with a noteworthy contribution by Pitt and Shephard (1999). Particle filtering and related Monte Carlo methods are still in development as can be learned from the recent review article of Creal (2012).

Textbook treatments of generalized state space models from both classical and Bayesian perspectives are presented by, among others, Harvey (1989: Section 6.6), West and Harrison (1997), Doucet et al. (2000), and Durbin and Koopman (2012).

This article is a revision of the previous edition article by D.A. Dickey, volume 23, pp. 15731–15735, © 2001, Elsevier Ltd.

Abstract

This article reviews some of the recent developments of the unit root time series and nonstandard limiting distributions. It gives an overview of this important topic, describes the impact of some of the recent progress, and briefly points to open challenges on subsequent research of this field.

Introduction

Unit root time series are ubiquitous in science, engineering, social sciences, and many other disciplines. Many scientific fields, especially in the social sciences, have used nonstationary time series for their problems. Research under the umbrellas of unit root, near unit root, nonstationary, nearly nonstationary, integrated, and near-integrated processes have been pursued actively. In essence, all these titles referred to time series with autoregressive roots on or near the unit circle. Since the seminal paper of White (1958), numerous attempts have been devoted to studying the asymptotic behavior of the least squares estimate (LSE) of the autoregressive coefficient of a unit root auto-regressive (AR) model. In this article, we focus on some of the strategic developments in this area related to statistics and offer some future directions and briefly point to open challenges. Succinct reviews on early developments on this subject can be found in Chan (2006, 2009) and the references therein.

This article is organized as follows. In Sections First-Order Model, Fisher's Information Number, and AR(p) Models, we review the developments of the unit root problem according to the limiting distributions of the LSE for AR(1) and AR(p) models. In Sections Negative Moment Bounds and Mean-Squared Prediction Error, we review the recent developments of negative moment bounds and mean-squared error predictions for nonstationary time series. This article also provides a road map for certain portions of the extensive literature on these topics, and the impact of some of the seminal work in related areas. Section Open Challenges contains ideas on new developments and some concluding remarks.

Unit Root Models

Developments of the unit root problem can be classified into three stages: estimation, inference, and model selection. Throughout these stages, there are some underlying common themes. The seminal paper of Lai et al. (1978) considered the strong consistency property of the LSE of a multiple regression model. Specifically, consider the model

$$y_i = \boldsymbol{\beta}^T \mathbf{x}_i + \varepsilon_i, \quad i = 1, 2, \ldots \qquad [1]$$

where the ε_i are unobservable errors, $\boldsymbol{\beta} = (\beta_1, \ldots, \beta_p)^T$ are unknown parameters, and y_i is the observable response corresponding to the design vector $\mathbf{x}_i = (x_{i1}, \ldots, x_{ip})^T$. Then

$$\mathbf{b}_n = \left(\sum_{i=1}^{n} \mathbf{x}_i \mathbf{x}_i^T\right)^{-1} \sum_{i=1}^{n} \mathbf{x}_i y_i \qquad [2]$$

is the LSE of the unknown parameter vector $\boldsymbol{\beta}$ based on the observations $\mathbf{x}_1, y_1, \ldots, \mathbf{x}_n, y_n$. Herein, the unobservable sequence $\{\varepsilon_n\}$ is assumed to be a martingale difference sequence with respect to an increasing sequence of sigma fields $\mathscr{F}_n$ satisfying a Lyapunov condition

$$\sup_n E(|\varepsilon_n|^\gamma | \mathscr{F}_{n-1}) < \infty \text{ almost surely (a.s.)} \quad \text{for some } \gamma > 2 \qquad [3]$$

By assuming that the design vector at stage n is adaptable, i.e., $\mathbf{x}_n$ is $\mathscr{F}_{n-1}$ measurable, Lai and Wei (1982a) proved the following.

Theorem 2.1. $\mathbf{b}_n \to \boldsymbol{\beta}$ *almost surely if*

$$\lambda_{\min}(n) \to \infty \text{ a.s. and } \log \lambda_{\max}(n) = o[\lambda_{\min}(n)] \text{ a.s.} \qquad [4]$$

where $\lambda_{\min}(n)$ and $\lambda_{\max}(n)$ denote respectively the minimum and the maximum eigenvalues of the design matrix $\sum_{i=1}^{n} x_i x_i^T$ at stage n.

This result extended the earlier work of Anderson and Taylor (1979) and constituted the turning point of the study of strong consistency in the regression literature. Based on this groundbreaking result, Lai and Wei (1982b, 1985) established the strong consistency of the LSE for a general AR model, irrespective to the location of its characteristic roots. This is one of the most general results concerning the strong consistency of the LSE of a general nonstationary AR(p) model. Tiao and Tsay (1983) subsequently considered the weak consistency property of the LSE for a nonstationary ARMA model. Recently, Nielsen (2005) extended Lai and Wei's result to the general VAR model with deterministic components.

First-Order Model

Back in 1958, White among others, first showed that the LSE of the autoregressive coefficient of a nonstationary AR(1) model, $y_t = \beta y_{t-1} + \varepsilon_t$, i.e., when the autoregressive coefficient β equals to one, converges in distribution to a function of

a stochastic integral of a standard Brownian motion. It turns out that this model has a strong bearing in the econometric literature in testing whether or not a time series is a random walk, the so-called unit root testing problem. After Dickey and Fuller (1979) established the form of this limiting distribution as a ratio of sums of identical and independently distributed (iid) random variables, the unit root testing problem became a topical issue in econometrics. Numerous articles were written on this topic and two elementary surveys on the statistical and econometric literature were given in Dickey et al. (1986) and Stock and Watson (1988), respectively.

With the strong consistency results, the next natural question is asymptotic inference. One is interested in the limiting distributions of the LSEs of the parameters of a general nonstationary autoregressive model. For the inference of the LSE $\widehat{\beta}_n$ of β, early developments can be summarized into the next theorem.

Theorem 2.2

1. $|\beta| < 1$, $\sqrt{n}(\widehat{\beta}_n - \beta) \Rightarrow N(0, 1-\beta^2)$, ε_t iid, finite variance, Anderson (1959).
2. $\beta = 1$, $n(\widehat{\beta}_n - \beta) \Rightarrow \frac{\int_0^1 W_t \, dW_t}{\int_0^1 W_t^2 \, dt}$, ε_t iid normal, White (1958).
3. $|\beta| > 1$, $\frac{\beta^n}{\beta^2-1}(\widehat{\beta}_n - \beta) \Rightarrow$ Cauchy, ε_t iid normal, Anderson (1959).

Likewise, if we consider the self-normalized t-statistic, then the preceding theorem can be rewritten as follows.

Theorem 2.3

$$\left(\sum_1^n y_t^2\right)^{1/2}\left(\widehat{\beta}_n - \beta\right) \Rightarrow \begin{cases} Z, & |\beta| < 1 \\ \mathscr{L}(0), & \beta = 1 \\ Z, & |\beta| > 1 \end{cases}$$

Herein, Z denotes a standard normal random variable, $\mathscr{L}(0) = \frac{\int_0^1 W_t \, dW_t}{\left(\int_0^1 W_t^2 \, dt\right)^{1/2}}$, W_t is a standard Brownian motion, and $\Rightarrow$ denotes weak convergence as $n \to \infty$. As will be seen in the next section, the self-normailzed factor $\sum_1^n y_t^2$ is the observed Fisher's information number and the order of its expected value plays a crucial role.

Fisher's Information Number

It turns out that the breakdown of asymptotic normality in the transition of $|\beta| < 1$ to $\beta = 1$ can be inferred through the order of the observed Fisher's information number. Let $I_n = \sum_{t=1}^n y_{t-1}^2$. Then direct calculation shows that

$$E(I_n) \approx \begin{cases} \dfrac{n}{1-\beta^2}, & |\beta| < 1 \\ n^2, & \beta = 1 \end{cases}$$

Based on this fact, Lai and Siegmund (1983) established the following result under a sequential sampling scheme.

Theorem 2.4. Lai and Siegmund (1983). Let $N_c = \inf\{n : I_n \geq c\}$. Then

$$(I_{N_c})^{1/2}\left(\widehat{\beta}_n - \beta\right) \Rightarrow Z$$

uniformly in β as $c \to \infty$.

This result indicates that when the Fisher's information number reaches a certain horizon c and when the horizon c tends to infinity, then uniform asymptotic normality for the LSE can be attained. Although this result carries a lot of theoretical gravity, most time series were not sampled sequentially with c tending to infinity. In practice, most of the time series would only be sampled with n tending to infinity. Nevertheless, Theorem 2.4 reveals that a key quantity to establishing the asymptotic result is given by the magnitude of the observed Fisher's information number I_n. If we need to know the asymptotic behavior of the LSE $\widehat{\beta}_n$, then we can take advantage of the behavior of I_n in a neighborhood of one. We quantify the closeness of β to one by maintaining the order of $E(I_n)$ in the vicinity of one. To this end, let $\beta_n = 1 - \gamma/a_n$. Direct calculation shows that

$$E(I_n) = \frac{n}{1-\beta_n^2} = \frac{na_n}{\gamma(2-\gamma/a_n)}$$

To maintain $E(I_n) \approx n^2$, we need to take $a_n = n$ and hence the nearly unstable model is characterized by using

$$\beta_n = 1 - \frac{\gamma}{n}$$

where γ is a nuisance parameter. In short, the near unstable AR(1) model becomes

$$y_t = \beta_n y_{t-1} + \varepsilon_t, \quad t = 1, \ldots, n, \; y_0 = 0, \; \beta_n = 1 - \frac{\gamma}{n} \quad [5]$$

Chan and Wei (1987) considered such an AR(1) model when the autoregressive coefficient converges to one asymptotically. Instead of a Brownian motion, Chan and Wei (1987) showed that the limiting distribution of the LSE of a nearly nonstationary AR(1) model converges weakly to a functional of an Ornstein–Uhlenbeck process. Specifically, considering a triangular array of first-order autoregressive processes as given in eqn [5], Chan and Wei derived the following theorem.

Theorem 2.5. Chan and Wei (1987). Let y_t follow a nearly unstable AR(1) model and consider the statistics $\widehat{\tau}_n = (\sum_1^n y_{t-1}^2)^{1/2}(\widehat{\beta}_n - \beta_n)$. Then

1. $\widehat{\tau}_n \Rightarrow \frac{\int_0^1 W_{\gamma,t} \, dW_t}{\left(\int_0^1 W_{\gamma,t}^2 \, dt\right)^{1/2}} := \mathscr{L}(\gamma)$, where $W_{\gamma,t}$ is the Ornstein–Uhlenbeck process. Furthermore,
2. $\mathscr{L}(\gamma) \Rightarrow Z$ as $|\gamma| \to \infty$.

This particular result encompasses the unit root case of White (1958) when $\gamma = 0$. In this case, the autoregressive coefficient $\beta_n = 1$ and $\mathscr{L}(0) = \int_0^1 W(t) \; dW(t)/(\int_0^1 W^2(t) \, dt)^{1/2}$, which is the limiting distribution of the Dickey–Fuller statistic. Using reproducing kernels, Chan (1988) further developed this limiting form as sums of iid random variables. The near-integrated notion was formulated with reference to the work of LeCam about limiting experiments in terms of contiguous alternatives. This idea was later explored by Jeganathan (1991, 1995), who generalized the near-integrated notion to a general AR(p) case and introduced the idea of Local Asymptotic Brownian Functional in studying optimality issues. Furthermore, part (2) of Theorem 2.5 indicates the limiting behavior of an explosive model, which was used by Phillips and Yu (2009) to study the issues of financial bubbles.

More recently, Buchmann and Chan (2007) combined the notions of long-memory and near nonstationarity and established the limiting distributions of the LSE under such a general setting, in which they made use of Malliavin calculus.

In a spectral setting, Dahlhaus (1985) considered both tapered and nontapered Yule–Walker estimates for near-integrated models. Since then, numerous extensions have been carried out by econometricians and statisticians. For example, on the statistical front, Cox and Llatas (1991) considered the M-estimation of a near nonstationary process, Pham (1992) and Ing (2001) studied the bias and prediction mean square error expansion of the LSE of a near unit root model, Basawa et al. (1991) investigated the bootstrap estimate of a unit root model, Larsson (1998) considered the Bartlett correction property of the unit root test statistics and Chan (1988) extended the notion of near unit root to a seasonal model. On the econometric front, the issues of testing for the unit root hypothesis for econometric series was considered in Phillips (1987) and Phillips and Perron (1988), among others. Many of these results were explored further by various people under the topics of trend breaks and cointegration. Interested readers can consult the review articles of Stock (1994) and Watson (1994) on these topics. Finally, it should also be pointed out that while extensive studies were pursued by statisticians and econometricians alike, one of the earlier developments in this problem was first given in the monograph of Arató (1982) and later in an unpublished thesis of Bobkoski (1983).

A closely related problem to the unit root AR(1) model is a unit root moving average order one (MA(1)) model given by

$$y_t = \varepsilon_t - \theta\varepsilon_{t-1} \qquad [6]$$

with $\{\varepsilon_t\}$ satisfying eqn [3]. Asymptotic properties of the maximum likelihood estimate (MLE) $\widehat{\theta}_n$ of the MA coefficient when $\theta = 1$ constitute an actively pursued area. Cryer and Ledolter (1981) first examined the consistency property of $\widehat{\theta}_n$. Davis and Dunsmuir (1996) derived the limiting distribution of the maximum likelihood estimator of θ under the unit root $\theta = 1$ and $\theta = 1 - c/n$ (for a constant $c > 0$) setups. Interestingly, there is a significant pile-up probability, i.e., $P(\widehat{\theta}_n = 1)$ has a nonzero limit for all values of $c > 0$. The limiting pile-up probabilities can be quite large especially for small values of c. Saikkonen and Luukkonen (1993) examined the testing for a moving average unit root issue. Using the idea of the so-called derived process, Chan and Tsay (1996) studied the limiting distribution of the MLE for a general unit root MA(q) model. A systematic account on the unit root moving average model is given in Chapter 8 of Tanaka (1996).

AR(p) Models

Chan and Wei (1988) considered the limiting distributions of the LSE of a general nonstationary AR(p) model when the characteristic roots lie on or outside the unit circle, each of which may have different multiplicities. This was the first comprehensive treatment of the LSE for a general nonstationary AR(p) model, and it was shown in Chan and Wei (1988) that the locations of the roots of the time series played an important role in characterizing the limiting distributions. Specifically, they considered a general nonstationary AR(p) model

$$y_t = \beta_1 y_{t-1} + \cdots + \beta_p y_{t-p} + \varepsilon_t \qquad [7]$$

In eqn [7], the autoregressive polynomial $\beta(z) = 1 - \beta_1 z - \cdots - \beta_p z^p$ has roots lying on or outside the unit circle. That is,

$$\beta(z) = (1-z)^a (1+z)^b \Pi_{k=1}^{\ell} \left(1 - 2\cos\theta_k z + z^2\right)^{d_k} \psi(z) \qquad [8]$$

where a,b,ℓ,d_k are nonnegative integers, θ_k belongs to $(0,\pi)$ and $\psi(z)$ is a polynomial of order $r = p - (a + b + 2d_1 + \cdots + 2d_k)$ that has all roots outside the unit disk.

When the underlying model is stationary with all roots lying outside the unit circle, classical central limit theorem type results can be obtained. But when the roots are of unit modulus, it turns out that the asymptotic distributions are characterized in terms of the integrated integrals of Brownian motions. The key idea in obtaining these results lies in analyzing the order of magnitude of the observed Fisher's information matrix. Note that the LSE of $\boldsymbol{\beta} = (\beta_1, \ldots, \beta_p)^T$ can be expressed as

$$\mathbf{b}_n = \left(\sum_{t=1}^{n} \mathbf{y}_{t-1}\mathbf{y}_{t-1}^T\right)^{-1} \sum_{t=1}^{n} \mathbf{y}_{t-1} y_t \qquad [9]$$

where $\mathbf{y}_t = (y_t, \ldots, y_{t-p+1})^T$ and $\mathbf{y}_0 = (0, \ldots, 0)^T$. Similar to the estimation problem, different characteristic roots carry different information. By transforming the original nonstationary AR model into components according to their characteristic roots, Chan and Wei (1988) were able to derive the precise form of the limiting distributions. During the course of this investigation, they also obtained an important result about the weak convergence of stochastic integrals (Theorem 2.4 in Chan and Wei, 1988), which is of independent interest and has many applications in different areas, see for example, Kurtz and Protter (1991). In addition, Chan and Wei also showed that different components are asymptotically uncorrelated and, as a result, a joint limiting law can be established. Specifically, using the notation of Chan and Wei (1988), the following theorem was established.

Theorem 2.6. Assume that $\{y_t\}$ follows eqn [7] with the characteristic polynomial satisfying eqn [8] and the innovation sequence $\{\varepsilon_t\}$ satisfying eqn [3]. Then as $n \to \infty$

$$Q^T G_n^T \left(b_n - \beta\right) \to_D \Big(\left(F^{-1}\xi\right)^T, \left(\tilde{F}^{-1}\eta\right)^T, \left(H_1^{-1}\zeta_1\right)^T, \ldots, \left(H_\ell^{-1}\zeta_\ell\right)^T, N^T\Big)^T$$

where $(F,\xi),(\tilde{F},\boldsymbol{\eta}),(H_1,\zeta_1), \ldots, (H_\ell,\zeta_\ell),N,G_n,Q$ are independent and defined in eqns (3.2), (3.3), and Theorem 2.2 of Chan and Wei (1988).

This result of Chan and Wei paved the way to the analysis of nonstationary processes and since then, numerous extensions have been conducted. Jeganathan (1991) generalized this idea to the near-integrated situations where the limiting distributions of the LSE are expressed in terms of iterated integrals of Ornstein–Uhlenbeck processes. When the underlying model has long-memory, Chan and Terrin (1995) extended this result to

functionals of fractional Brownian motions, while Chan and Zhang (2012) considered the case when the innovations are heavy-tailed. In a recent paper, Buchmann and Chan (2013) introduced a Jordan canonical decomposition idea to combine the notions of near nonstationarity and long-memory behavior for such a general AR(p) model. Finally, extensions of this result to vector AR processes are given in Tsay and Tiao (1990) and to processes with deterministic trends in Chan (1989b). On the econometric front, Theorem 2.4 provides a fundamental tool in analyzing cointegrated systems. Comprehensive reviews on cointegrated vector autoregressions are given in Johansen (2009). A useful introduction of using cointegration ideas in statistical arbitrage is given in Chapter 15 of Chan (2010).

Model Selection

Consider the stochastic regression model eqn [1] again. A natural problem is to study the performance of the LSEs in prediction and formulated the so-called predictive principle for model selection. By analyzing the order of the cumulative predictive errors

$$C_n = \sum_{k=1}^{n} \left(\boldsymbol{\beta}^{\mathrm{T}}\mathbf{x}_k - \mathbf{b}_{k-1}^{\mathrm{T}}\mathbf{x}_k\right)^2 = \sum_{k=1}^{n} \left(\widehat{\varepsilon}_k - \varepsilon_k\right)^2$$

where $\widehat{\varepsilon}_k = y_k - \widehat{y}_k = y_k - \mathbf{b}_{k-1}^{\mathrm{T}}\mathbf{x}_k$ is the one-step prediction error, Wei (1987, 1992) observed that the term C_n plays a crucial role for model selection. For a succinct review on this issue, we refer the readers to Chan (2009) and the references therein.

Negative Moment Bounds

Subsequent to Wei's prediction error principle, further developments can be found in Ing (2007) and Ing et al. (2010). In this section, we review some of the recent developments about prediction errors calculations for unit root time series. It turns out that this important problem is related to the negative moment bounds of the underlying time series. Specifically, let $y_1, \ldots, y_n$ be generated from the stochastic regression model,

$$y_t = g_t(\boldsymbol{\eta}_0) + \varepsilon_t, \quad t = 1, \ldots, n \qquad [10]$$

where $\boldsymbol{\eta}_0 = (\alpha_{0,1}, \ldots, \alpha_{0,p1}, \beta_{0,1}, \ldots, \beta_{0,p2})^T$ is an unknown coefficient vector and $g_t(\boldsymbol{\eta}_0)$ has the auto-regressive moving average (ARMA) representation

$$g_t(\boldsymbol{\eta}_0) = \alpha_{0,1}y_{t-1} + \cdots + \alpha_{0,p_1}y_{t-p_1} - \beta_{0,1}\varepsilon_{t-1} - \cdots - \beta_{0,p_2}\varepsilon_{t-p_2} \qquad [11]$$

with the initial conditions $y_t = \varepsilon_t = 0$ for all $t \le 0$. Define

$$\widehat{\boldsymbol{\eta}}_n = \arg\min_{\eta\in\Pi} \sum_{t=1}^{n} [y_t - g_t(\boldsymbol{\eta})]^2$$

where $\prod \subset R^{p_1+p_2}$ is a compact set that includes $\boldsymbol{\eta}_0$ as an interior point and whose elements $\boldsymbol{\eta} = (\alpha_1, \ldots, \alpha_{p1}, \beta_1, \ldots, \beta_{p2})^T$ satisfy the following properties: for all $|z| \le 1$,

$$A_{1,\boldsymbol{\eta}}(z) = 1 - \sum_{j=1}^{p_1} \alpha_j z^j \neq 0, \quad A_{2,\boldsymbol{\eta}}(z) = 1 - \sum_{j=1}^{p_2} \beta_j z^j \neq 0$$

$A_{1,\boldsymbol{\eta}}(z)$ and $A_{2,\boldsymbol{\eta}}(z)$ have no common zeros with $\left|\alpha_{p_1}\right| + \left|\beta_{p_2}\right| > 0$

An important issue is to investigate the moment convergence of the LSE, in particular the order of

$$\mathrm{E}\left\|n^{1/2}(\widehat{\boldsymbol{\eta}}_n - \boldsymbol{\eta}_0)\right\|^q, q \ge 1 \qquad [12]$$

It turns out that the uniform negative moment bound for $n^{-1}\sum_{t=1}^{n}[g_t'(\boldsymbol{\eta})]^2$, that is,

$$\mathrm{E}\left\{\sup_{\boldsymbol{\eta}\in B_{\delta_1}(\boldsymbol{\eta}_0)} \left(n^{-1}\sum_{t=1}^{n}\left[g_t'(\boldsymbol{\eta})\right]^2\right)^{-q}\right\} = O(1), q \ge 1 \qquad [13]$$

plays a crucial role in establishing eqn [12], where $B_{\delta 1}(\boldsymbol{\eta}_0) = \{\boldsymbol{\eta}:|\boldsymbol{\eta} - \boldsymbol{\eta}_0| < \delta_1\}$ for some $\delta_1 > 0$.

For the ARMA model $\{y_t\}$ defined in eqn [10], we have the following theorem.

Theorem 3.1. Chan and Ing (2011). Assume model [10], with $g_t(\cdot)$ as defined in eqn [11] and ε_t being independent random variables satisfying $\mathrm{E}(\varepsilon_t) = 0$ and $\mathrm{E}(\varepsilon_t^2) = \sigma^2$ for all $t \ge 1$. Moreover, assume that there exist positive constants α_1, ξ and M_1 such that for any $0 < s_2 - s_1 \le \xi$

$$\sup_{1\le m\le t<\infty, \|\mathbf{v}\|=1} \left|F_{t,m,\mathbf{v}}(s_2) - F_{t,m,\mathbf{v}}(s_1)\right| \le M_1(s_2 - s_1)^{\alpha_1}$$

where $\mathbf{v} \in R^m$ and the function $F_{t,m,\mathrm{v}}(\cdot)$ denotes the distribution function of the scalar product $\mathbf{v}^T(\varepsilon_t, \cdots, \varepsilon_{t+1-m})^T$. Then,

$$\mathrm{E}\left\|n^{1/2}(\widehat{\boldsymbol{\eta}}_n - \boldsymbol{\eta}_0)\right\|^q = O(1), q \ge 1 \qquad [14]$$

As an application of this Theorem, an asymptotic expression for the mean-squared prediction error (MSPE) of $\widehat{\boldsymbol{\eta}}_n$, $\mathrm{E}\{y_{n+1} - g_{n+1}(\widehat{\boldsymbol{\eta}}_n)\}^2$, is given in the next Theorem.

Theorem 3.2. Chan and Ing (2011). Assume that the assumptions of the preceding Theorem hold. Moreover, let ε_t be iid random variables satisfying for some $q_1 > 18$,

$$\mathrm{E}|\varepsilon_1|^{q_1} < \infty$$

Then,

$$\lim_{n\to\infty} n\left[\mathrm{E}\{y_{n+1} - g_{n+1}(\widehat{\boldsymbol{\eta}}_n)\}^2 - \sigma^2\right] = (p_1 + p_2)\sigma^2 := \overline{p}\sigma^2$$

Subsequently, this result has been extended to the long-memory situation. In particular, when $\{y_t\}$ follows an auto-regressive fractionally integrated moving average (ARFIMA) model such as

$$\alpha(B)(1 - B)^{d_0}y_t = \beta(B)\varepsilon_t \qquad [15]$$

where $\alpha(B)$ and $\beta(B)$ are defined as before and $d_0 \in R$, we arrive at the next Theorem. Unlike the traditional setting, note that d_0 is no longer restricted to $[-1/2, 1/2]$.

Theorem 3.3. Chan et al., (2013). Assume that $\{y_t\}$ satisfies an ARFIMA model as given in eqn [15]. Further, let $d_0 \in$, $D = [L, U]$ with $-\infty < L < U < \infty$. Under certain regularity conditions as those given in Theorem 3.1, the negative moment bound eqn [14] holds, that is

$$\mathrm{E}\left\|n^{1/2}(\widehat{\boldsymbol{\eta}}_n - \boldsymbol{\eta}_0)\right\|^q = O(1), q \ge 1$$

Mean-Squared Prediction Error

In this section, we apply the result of the Section Negative Moment Bounds to study the prediction problem. To predict y_{n+h}, $h \geq 1$, based on $y_1, \ldots, y_n$, consider

$$\begin{aligned} p_t(\boldsymbol{\eta}, y_{t-1}, \ldots, y_1) &:= y_t - \varepsilon_t(\boldsymbol{\eta}) \\ &= \left[1 - (1-B)^d A_{1,\eta}(B) A_{2,\eta}^{-1}(B)\right] y_t \end{aligned}$$

The one-step conditional sum of squares (CSS) predictor of y_{n+1} is given by

$$\begin{aligned} \widehat{y}_{n+1}(\widehat{\boldsymbol{\eta}}_n) &= p_{n+1}(\widehat{\boldsymbol{\eta}}_n, y_n, \ldots, y_1) \\ &= y_{n+1} - \varepsilon_{n+1}(\widehat{\boldsymbol{\eta}}_n) = \widehat{\boldsymbol{\eta}}_n^T \mathbf{y}_n \end{aligned}$$

Note that $y_{n+1}(\widehat{\boldsymbol{\eta}}_n)$ depends solely on $y_1, \ldots, y_n$. Further, y_{n+h}, $h \geq 2$, can be predicted recursively by the h-step CSS predictor,

$$\widehat{y}_{n+h}(\widehat{\boldsymbol{\eta}}_n) := p_{n+h}(\widehat{\boldsymbol{\eta}}_n, \widehat{y}_{n+h-1}(\widehat{\boldsymbol{\eta}}_n), \ldots, \widehat{y}_{n+1}(\widehat{\boldsymbol{\eta}}_n), y_n, \ldots, y_1)$$

which is sometimes known as the plug-in predictor. For the one-step MSPE, it is shown in Chan et al. (2013) that

$$\lim_{n\to\infty} n\left[\mathrm{E}\left\{y_{n+1} - \widehat{y}_{n+1}(\widehat{\boldsymbol{\eta}}_n)\right\}^2 - \sigma^2\right] = \bar{p}\sigma^2 := (p_1 + p_2 + 1)\sigma^2$$

This result shows that the second-order MSPE of $\widehat{y}_{n+1}(\widehat{\boldsymbol{\eta}}_n)$ only depends on the number of estimated parameters; the dependent structure of the underlying process is irrelevant as far as the second-order MSPE is concerned. This result not only is interesting, but it is also intriguing and revealing when compared to the second-order MSPE of the least squares (LS) predictor for integrated AR models. Assume that a forecaster thinks that the true model is possibly an integrated AR(p_1) model,

$$\begin{aligned} &\left(1 - \tilde{\alpha}_1 B - \cdots - \tilde{\alpha}_{p_1} B^{p_1}\right) y_t = \varepsilon_t \\ &(1-B)^{v_0}\left(1 - \theta_1 B - \cdots - \theta_{p_1 - v_0} B^{p_1 - v_0}\right) y_t = \varepsilon_t \end{aligned} \qquad [16]$$

where $1 - \theta_1 z - \cdots - \theta_{p_1 - d} z^{p_1 - v_0} \neq 0$ for all $|z| \leq 1$ and $v_0 \in \{0, 1, \ldots, p_1\}$ is unknown. Then it is natural for this forecaster to predict y_{n+1} using the LS predictor $\tilde{y}_{n+1}$, in which $\tilde{y}_{n+1} = y_n^T(p_1)\tilde{\boldsymbol{\alpha}}_n(p_1)$ with $\mathbf{y}_t^T(p_1) = (y_t, \ldots, y_{t-p_1+1})$ and $\tilde{\boldsymbol{\alpha}}_n(p_1)$ satisfying

$$\sum_{t=p_1}^{n-1} \mathbf{y}_t(p_1)\mathbf{y}_t^T(p_1)\tilde{\boldsymbol{\alpha}}_n(p_1) = \sum_{t=p_1}^{n-1} \mathbf{y}_t(p_1) y_{t+1}$$

Suppose that there is another forecaster having doubts on whether the v_0 in eqn [16] is really an integer. This forecaster chooses the more general alternative,

$$\left(1 - \alpha_1 B - \cdots - \alpha_{p_1} B^{p_1}\right)(1-B)^{d_0} y_t = \varepsilon_t$$

where $L_1 \leq 0 \leq d_0 \leq p_1 \leq U_1$ with $-\infty < L_1 < U_1 < \infty$ being some prescribed numbers. This model includes eqn [16] as a special case and the forecaster naturally chooses CSS predictor.

If v_0 is an integer, according to Ing et al. (2010), the MSPE of the LS predictor satisfies

$$\lim_{n\to\infty} n\left[\mathrm{E}\left\{y_{n+1} - \tilde{y}_{n+1}\right\}^2 - \sigma^2\right] = (p_1 + v_0^2)\sigma^2$$

On the other hand, according to the aforementioned result of Chan et al. (2013), the MSPE of the CSS predictor satisfies

$$\lim_{n\to\infty} n\left[\mathrm{E}\left\{y_{n+1} - \widehat{y}_{n+1}(\widehat{\boldsymbol{\eta}}_n)\right\}^2 - \sigma^2\right] = (p_1 + 1)\sigma^2$$

While the second-order MSPE of the LS predictor $\tilde{y}_{n+1}$ increases with the dependence structure (i.e., v_0 increases), the second-order MSPE of the CSS $\widehat{y}_{n+1}(\widehat{\boldsymbol{\eta}}_n)$ does not change with v_0. This observation reveals the interesting fact that for integrated AR models, the popular LS predictor is inferior to the CSS predictor.

For multistep MSPE, Chan et al. (2013) established the following result.

$$\begin{aligned} &\lim_{n\to\infty} n\left\{\mathrm{E}[y_{n+h} - \widehat{y}_{n+h}(\widehat{\boldsymbol{\eta}}_n)]^2 - \sigma_h^2(\boldsymbol{\eta}_0)\right\}/\sigma^2 \\ &\quad = \underline{f}_h(p_1, p_2) + \underline{g}_h(\boldsymbol{\eta}_0) + 2J_h(\boldsymbol{\eta}_0) \\ &\quad = \text{ARMA} + I(d) + \text{ARMA and } I(d) \text{ (joint effect)} \end{aligned}$$

Unlike the one-step MSPE situation, the dependence structure has a substantial effect on the multistep MSPE. Consider the pure $I(d)$ case. It follows that for any $d_0 \in R$, there exists $0 < C_{1,d_0} \leq C_{2,d_0} < \infty$ such that

$$\begin{aligned} C_{1,d_0} h^{-1+2d_0} &\leq n\mathrm{E}[y_{n+h} - \widehat{y}_{n+h}(\widehat{\boldsymbol{\eta}}_n)]^2 - \sigma_h^2\left(\boldsymbol{\eta}_0\right)\Big\}\Big/\sigma^2 \\ &\leq C_{2,d_0} h^{-1+2d_0} \end{aligned}$$

which shows that for $h > 1$, a larger d_0 (stronger dependence) gives rise to a larger second-order MSPE.

What about the least squares method? Suppose that a random walk model, $y_t = \alpha y_{t-1} + \varepsilon_t$ for $\alpha = 1$ is modeled by an integrated order d (I(d)) process, $(1-B)^d y_t = \varepsilon_t$, in which $d = 1$ corresponds to the true model. Then

$$\lim_{n\to\infty} n\left\{\mathrm{E}\left[y_{n+h} - \widehat{y}_{n+h}\left(\widehat{d}_n\right)\right]^2 - h\sigma^2\right\} = \sigma^2 \quad \text{for } h = 1$$

and the same limit is smaller than

$$\left[4.87h + (1 + \log h)^2 - 2(1 + \log 2h)\right]\sigma^2 \quad \text{for } h \geq 2$$

Let $\tilde{y}_{n+h}$ be the h-step LS predictor of this AR(1) model. It follows from Ing et al. (2010) that

$$\lim_{n\to\infty} n\left\{\mathrm{E}(y_{n+h} - \tilde{y}_{n+h})^2 - h\sigma^2\right\} = 2h^2\sigma^2$$

which is larger than σ^2 when $h = 1$, and larger than $[4.87h + (1 + \log h)^2 - 2(1 + \log 2h)]\sigma^2$ when $h \geq 2$. Hence, $\widehat{y}_{n+h}(\widehat{d}_n)$ is always better than $\tilde{y}_{n+h}$ in terms of the MSPE.

As far as estimations are concerned, the situation is completely reversed, however. The LSE converges much faster to 1 than $\widehat{d}_n$ under the random walk model. This example reminds us that when the true model belongs simultaneously to several different parametric families, the optimal choice of parametric families can vary according to different purposes of statistical inferences, e.g., estimation, testing, and prediction, etc. Is there a general rule? The above result suggests the following phenomena.

- More Fisher information, less estimation risk.
- Less Fisher information, less prediction risk.

This general principle seems to indicate that as $n \to \infty$,

$$n \times (\text{One-stepMSPE} - \sigma^2) \to \frac{1}{\log n}[\log\det(\text{Fisher Information Matrix})]$$

in probability.

Open Challenges

Although the field of time series in general and the subject of unit root time series in particular have been going through rigorous developments for the last few decades, there are still many open and interesting areas to be explored. In nonstationary time series, the recent popularity of long-memory models remains an open and challenging field, see Chan and Terrin (1995) and Buchmann and Chan (2007, 2013). Equally important is the area of model selection and prediction errors. In particular, we are faced with the challenges of:

- How to develop consistent model selection criteria for ARFIMA(p_1,d,p_2) with $d \in R$? What about Bayesian Information Criterion (BIC)-type criteria?
- How to develop asymptotically efficient criteria for ARFIMA(∞,d,0) with $d \in R$? Should we still use Akaike Information Criterion (AIC)?

The recent development of Chan and Ing (2011) and Chan et al. (2013) offer some insights into solving these issues. In summary, this article only offers a modest account for some of the developments of unit root time series. As witnessed by the aforementioned discussions, the subject of unit root time series has been manifested into different forms and found applications in areas such as engineering and econometrics. Through asymptotic inference, the scope of unit root time series has been greatly broadened and many profound challenges still remain to be resolved, which in turn will push the subject into new frontiers.

Time Use and Gender

Tanja van der Lippe, Utrecht University, Utrecht, The Netherlands

Abstract

Men and women have to make decisions on how to use their time, as a day has only 24 h, or rather time is limited. It is best measured by using the time diary method. The traditional gender division of time use has changed over the last decades: more women have paid jobs and the division of household labor has become more equal due to the decline in domestic work of women. Explanations of gender differences in time use are given by new home economics, exchange theory, and gender role theory. In addition to individual factors, differences in the institutional context are important as well for time use decisions of men and women.

Time Use

Men and women have to make decisions on how to use their time, as a day has only 24 h, or rather time is limited. Activities men and women make decisions about can be divided into paid work, domestic work and child care, personal obligations, and leisure. Time has become an increasingly scarce good; newspapers and other media abound with stories suggesting that time pressure is becoming a real epidemic. This article discusses how time use is measured and the patterns of time use of men and women and provides explanations of gender differences.

The Measurement of Time Use

To understand time use of men and women, it can be categorized in several ways. If one is interested in paid work and leisure, a distinction is made between work and nonwork activities. With respect to the division of labor between husbands and wives, the most frequently used division is between paid work, domestic work and child care. It is evident what is meant by paid work, and most authors use more or less the same description. However, household labor can be defined in a variety of ways. Naturally, cooking and cleaning are domestic tasks, but it is not clear how to classify activities that are part leisure and part work, such as vegetable gardening, gourmet cooking, or playing with the children. Leisure is a broad category, including indoor activities like reading books, watching television and gaming, outdoor activities like sporting, but also social contacts and going out for dinner. Personal obligations often form a kind of residual category, including activities like sleeping and eating at home.

The most accurate and reliable way to measure the time use of people is the time diary method (Andorka, 1987; Gershuny, 2000; Van der Lippe et al., 2011). In this approach, respondents are asked to keep records of what they were doing at all times for a day or more. In some studies the main activity is noted in fixed interval units (e.g., in quarters of an hour) while in others intervals are left free (i.e., starting and finishing times are indicated). The period of time when the diary is kept also differs. In some cases respondents are only required to keep a diary for a single day, while in others they are asked to do so for a whole week. The time diary method prevents respondents from exaggerating the durations of their favorite activities while neglecting the time devoted to day-to-day concerns and trivialities. Thus, the actual subject being studied is not overstated, which sometimes happens when specialized questionnaires are used. A serious limitation of time diaries is the difficulty in dealing with more than one activity performed simultaneously. For example, people may cook dinner while supervising children, or sew while watching television. Another method to measure patterns of time use is asking direct questions that require men and women to estimate their usual time spent on a list of activities. In order to help the respondent, in these questionnaires often domestic work is distinguished into some clear categories like cooking, cleaning, doing the laundry, and shopping. Analyses of the data from such questionnaires and the Experience Sampling Method show that husbands overestimate their own time, but that their wives make accurate estimates of husbands' time on domestic work. With respect to the amount of time wives spend on domestic work, Lee and Waite (2005) conclude that both wives and husbands may substantially overestimate this.

Time Use Patterns

There has been a traditional gender division of time consuming activities within Western societies: women used to do most of the domestic work and child care, whereas men worked for pay the whole day and were responsible for providing family income. This has changed substantially in recent decades. At the beginning of the twenty-first century, women are more likely to have a paid job than to be housewives in almost all industrialized countries, a statement, one could not imagine just after World War II (Van der Lippe, 2010). Despite the overall increase in levels of women's employment, large differences exist between countries in the northern continents. Nordic countries, such as Sweden and Denmark, have had higher levels of female labor force participation than other Western countries for a long time. The Anglo-Saxon countries, such as the United States and the UK were runners up, while in Italy still only half of the active female population has a paid job. The Netherlands has had a low level of women's

employment for a long time, but recently the number of working women increased sharply. For eastern Europe, the picture is different. The communist ideology, established after the World War II in eastern Europe with the exception of Russia, forced many women to enter the labor market. In the 1960s already three quarters of the women had a paid job. Activity rates of women decreased after the transition from socialism in these countries and they are now among the lowest in Europe (Eurostat, 2012).

Despite the overall increase in the level of women's employment, there are considerable differences between countries in the number of hours per week that women work for pay. While part-time work is common in Norway, United Kingdom, and the Netherlands, employed women in Italy, Greece, Spain, and Portugal almost all work full-time. Also about 80% of US employed women work full-time (Van der Lippe, 2010). In eastern Europe part-time work simply did not exist before the political turnover. After 1989, full-time work is still the rule in the former socialist countries (Van der Lippe and Fodor, 1998).

The growth in paid work of women is linked to the often noted decline in domestic work on the part of women in Western countries (Gershuny, 2000). Compared to this large change in women's time use in the west in general, there has been hardly any change in men's time use. Although there has been a small increase in men's domestic work, these changes are trivial compared to the increase in women's employment and the reduction in their domestic work. The more equal division of domestic work between husbands and wives nowadays is less a result of an increase in men's domestic work and more because of the reduced time women spend on household duties (Treas and Drobnic, 2010). When men perform domestic tasks, they disproportionately do what are often considered more 'pleasant' tasks (e.g., child care and cooking rather than cleaning the toilet).

Although the amount of leisure time differs less between the sexes as between those in paid and domestic work, the nature of leisure time is different (Mattingly and Bianchi, 2003). Women are more disturbed in their leisure time by other time activities, probably due to their responsibility for children during their leisure time. Some authors show that the amount of leisure time for both men and women has increased over the last decades due to a decline in market work hours and home production work hours (Aguiar and Hurst, 2007). Others show a decline in leisure time among parents, which is sharper for mothers than fathers suggesting that mothers give up leisure time so they can spend more time to paid work ánd child care (Sayer, 2005). Results show that partners now spend more time together engaged in various leisure activities than they did in the past, not only in percentages but also in absolute number of minutes (Voorpostel et al., 2010).

Explanations for the Different Use of Time by Gender

A rich body of literature is available on men and women's allocation of time (Gershuny, 2000; Bianchi et al., 2000; Shelton and John, 1996). Many study explanations of men's and women's division of paid and domestic work (Bianchi and Milkie, 2010; Hook, 2006; Van der Lippe et al., 2011) and some of these studies compare thereby several countries (Georgas et al., 2006).

The Individual Level

An important theoretical explanation of time allocation has been provided by economic theory (Becker, 1965). Given their constraints or resources, human beings strive for goals and make choices in their time use. An obvious resource within economic theory is human capital. Human capital constitutes the knowledge and skills that increase an individual's productivity. Education is often considered the most important form of human capital. So, for highly educated women and men, it is appealing to devote a great deal of their time to working in the labor market, since the benefits in terms of money and status can be high. This implies less time for domestic work and nonwork activities. To understand the division of paid and domestic work between husbands and wives, economic theory is valuable as well. Within the 'new home economics,' explicit attention is given to the importance of household activities (Becker, 1981). In this model of household production, households are viewed as small factories that, within the time and income limitations, make every effort to maximize their output. If the husband can earn more money and is less productive in household labor than his wife, the husband will specialize in paid labor and the wife in household labor (Becker, 1981). In Becker's view, which does not highlight any conflicts of interest between spouses but assumes altruism, each spouse specializes in what will make his or her best contribution to the family.

Sociological exchange theory (Blood and Wolfe, 1960; Brines, 1994) provides a different account of spousal specialization. Differences in resources, such as education and income, are considered to be a main cause for the different time use by men and women. Assuming that individuals do not like to do domestic work, this theory predicts that the spouse with the greater resources will have more power and will use it to minimize his or her domestic work. Thus the predictions are similar to those of the new home economics theory that spouses with higher relative earnings will do less household work, but the reasoning is different. Whereas in economic theory, each spouse chooses between market and household work in order to maximize contributions to the family, exchange theory typically treats employment and earnings as exogenous and examines how they affect bargaining power, and sees doing household work as an indication of less power. Research supports the notion that men's contribution to housework reduces the higher their earnings relative to female spouses (Bittman et al., 2003; Greenstein, 2000; Presser, 1994), although American men who are economically dependent on their wives compensate by adopting traditional behaviors in the household (Greenstein, 2000; Brines, 1994). Relative education is related to division of housework in a same way, implying that men of higher educated women do a higher proportion in housework (Bianchi et al., 2000). Results with respect to the link between the participation of women in paid labor and the division of household labor show that hours of female paid work have a strong negative effect on women's

domestic work but hardly any effect on men's time spent on domestic duties (Van der Lippe, 2010).

Another important theoretical perspective emphasizes gender specific socialization (Presser, 1994; Greenstein, 2000). It is not such a long time ago that women were socialized to be mothers and housewives and men to be wage-earners and support the family. More recently there is a great deal of variation in the degree of gender traditionality of socialization. Research suggests that men who adhere to traditional sex roles contribute less to household tasks than men whose sex roles are nontraditional (Kamo, 1988; Fuwa, 2004) and it has also been noted that women with modern role expectations do more paid and less domestic work (Presser, 1994). However, doing gender perspectives argue that household duties are perceived as 'women's work,' so that the effect of full-time paid work of the women on male participation in household work might be less than expected.

These theories can also partly explain the change in time use of men and women in recent decades. Given that the educational level of women all over the Western world has increased and is nowadays comparable to the level of men, according to the resource or productivity argument it has become attractive for women to spend more time on paid work. Consequently, they have less time available for domestic work and leisure. Furthermore, attitudes in the Western world have changed. Nowadays, working women are accepted in society and fathering has become one of the opportunities for men. According to the sex-specific socialization, it has become more likely as well that men carry more of the domestic workload than some decades ago, and women make a career. Indeed we do see an increase in time spent in child care by men, but rather unexpectedly also by women. Given the sociological and economic explanations, one would expect the opposite for women. It might be that the psychological meaning of children has changed. Children in our modern society are a highly valued 'good,' in which one wishes to invest a great deal of time. Moreover, the growing threat of the environment might play an important factor. The number of cars has increased continuously with the consequential danger of teaching children to play unattended or travel to activities alone. Finally, it might be an artifact of the methodology, due to the fact that only first activities are reported. Full-time housewives in unmechanized households used to do several household and caring tasks simultaneously, but reported only the first activity.

The Institutional Level

In addition to individual factors, differences in the institutional context are important for time use decisions of men and women. Although time use decisions are made on a micro level, the institutional context of a country can facilitate or restrict a certain time-use decision. Increasingly it is studied to what extent individual-level explanations hold in different contexts. There are differences among Western countries, which become clear using Esping-Anderson's typology (1990) of Welfare State regimes (liberal, conservative, social democratic), or related more gender-friendly typologies. In social democratic countries, such as the Scandinavian ones, public child care facilities are more extensive and women are stimulated more to have a paid job. In conservative countries, for a long time, women were not encouraged to have a paid job, and consequently child care was not available. In countries with less well-developed child care arrangements, women with young children are less likely to be employed than women with older children (Gornick et al., 1998). Based on a review of studies between 2000 and 2009 into household labor, Lachance-Grzela and Bouchard (2010) show that there is only some evidence supporting the idea that political efforts and social policies can modify the behaviors that occur in the home, but results are inconsistent. National contexts in which female empowerment is greater and in which structures advocate gender equity tend to favor egalitarian allocations of household labor within couples more (Lachance-Grzela and Bouchard, 2010). Moreover, lagged institutional accomodations to female employment is related to more gender equality in household division of labor (Treas and Tai, 2012).

In addition, macro indicators interact in a more significant way with micro indicators for the explanation of paid work than for the explanation of housework. In countries with a large economic development, higher educated women do more paid work – it seems rewarding for them in terms of money and status to spend much time on the labor market. In these economies, the family phase is important as well: for women having children implies that less time is spent on the labor market. For men, this is only true when having young children. Married women spend less time on paid labor, and unexpectedly this is also true for married men (Van der Lippe et al., 2011). Is this an emancipation effect of highly developed economies? More research is needed to investigate the relation between highly developed economies and part-time work of both men and women. In line with the disappearing boundaries between countries and states, due to the increase in communication and information technology, comparative studies on time use become increasingly important. At this moment, information is available on many Western industrialized countries, but one can only hope to compare their figures with those of Asian, South American, and African countries.

Time Use and Time Pressure

As balancing work with family life has become important nowadays, increasingly attention is also paid to feelings of time pressure. Many people feel down between work and family, not only because their households increasingly juggle competing responsibilities, but also because job expectation and parenting standards have becoming more demanding (Van der Lippe, 2007). In two-earner families, both partners are exposed to the greed associated with the jobs in which they work, and thus both will bring the restrictions imposed by their work situation to the time allocation in the household. Consequences range from feelings of stress, work–home interference, time pressure, and fatigue to burnout and other health problems. Spending much time on paid work and domestic duties implies more time pressure for both men and women, although women in general experience more time pressure.

Time Use and Resource Consumption

Henrike Rau, School of Political Science and Sociology, National University of Ireland, Galway, Ireland

Abstract

The ways in which people view and use time have very real material consequences that both shape and reflect the relationship between human society and the physical environment, thereby affecting sustainability transitions. More or less resource-intensive time cultures, that is, shared repertoires of time-related meanings and solutions to everyday problems, coexist both within and between countries. Moreover, they often cut across other socioeconomic and cultural fault lines such as class, gender, and rural–urban divisions. Having remained largely underresearched in the past, the recent 'temporal turn' in the social sciences has highlighted these time-cultural differences and their social and ecological impacts.

Introduction

The ways in which people use their time have very real material consequences that both shape and reflect the relationship between human society and the physical environment. For example, novel production and consumption practices afforded by the discovery of fossil fuels and parallel changes in the socioeconomic structures of societies such as Britain and Germany in the eighteenth and nineteenth-century are claimed to have initiated an acceleration and desynchronization of everyday life (Rosa, 2005). On the other hand, predictions by advocates of modern time management that time-saving technologies will radically reduce working hours and enhance people's quality of life did not materialize, partly because of the intensification of work and consumption whereby material and time-related rebound effects cancel out many technology-aided efficiency gains. Interestingly, the fundamental question of how people spent the time they saved and how this impacts society and the environment has never been satisfactorily answered.

Recent sustainability debates among academics, policymakers, and practitioners have highlighted this close connection between material consumption and human time use, albeit often in an unsystematic way, resulting in calls for a radical transformation of how people view and use their time (Jackson, 2009; Schor, 2010; cf Rau and Edmondson, 2013 for an overview). Bottom-up sustainability initiatives in many western societies such as efforts toward downshifting, voluntary simplicity movements, and collaborative consumption networks incorporate more or less radical changes in human time use. Many of these proposals imply a transformation of people's time culture, that is, their shared repertoires of time-related meanings and solutions to everyday problems (Rau, 2004), although this is not always made explicit. Proposals abound for changes in people's time horizon, a shift away from short-term thinking toward long-term planning, a deceleration of everyday life, and a reallocation of temporal resources away from consumption and toward nonconsumerist activities such as voluntary work or 'quality time' with others (cf Rau and Edmondson, 2013).

Yet others argue for the temporal reorganization of society through changes in the political conditions and power relations that underpin the temporal-spatial ordering of human social life. For example, Mückenberger's research on urban temporal policies and their influence on citizens' quality of life captures historical and contemporary links between governance, citizenship, and time (e.g., Boulin and Mückenberger, 1999; Mückenberger, 2010, 2011; Läpple et al., 2010). Recognizing the centrality and significance of time organization and 'time-welfare' for social cohesion and quality of life, he advocates time policies, that is, deliberate political efforts to enhance people's everyday time-related conditions (Mückenberger, 2011). In addition, there is evidence of an emergent temporal-spatial transformation of towns and cities in Europe and beyond. Recent work by Pink and Servon (2013) records the growing popularity of the Slow City (Cittaslow) movement in Europe as both a deceleration counternarrative and a novel approach to urban development. They argue that Cittaslow successfully connects (experiences of) the time-related qualities of a town or city and the quality of life of its citizens. Cittaslow exemplifies the increasingly diverse range of proposals for the creation of a new (urban) time culture, to counteract the negative implications of unfettered acceleration. The success, or otherwise, of such efforts to influence the temporal topography of cities requires coordinated social, institutional, and material transformations, including changes in urban form that foster more sustainable time use.

The remainder of this article is divided into four principal parts. Initially, it examines important connections between people's time use and their consumption of material and nonmaterial resources. Subsequently, it presents evidence for the continued coexistence of distinct time cultures both within and across countries, which in turn require different material resources and which produce more or less sustainable ecological footprints. Thirdly, the chapter critically examines proposals for a more just and sustainable society beyond the 'growth logic' of capitalism that call for a radical shift in time use and time culture. It concludes with a general outlook regarding the link between time use and resource consumption in theory, research, and practice.

Connections between Time Use and Resource Consumption

The complexity of the relationship between people's time use and their consumption of material and nonmaterial resources and its potential implications for society and the environment

cannot be overestimated. Records of both historical and recent transformations in the organization of time and associated changes in its allocation to different activities reveal this. Many developed and developing countries now rely on clock time as their main source of temporal reference and societal synchronization, replacing alternative modes of time reckoning that rely on natural pacers such as diurnal and lunar cycles, seasons and cycles of growth, and decay (Adam, 1996, 1998). The resulting discrepancy between natural cycles and social pacers in many modern capitalist societies, made possible through the availability of cheap fossil fuels, more efficient industrial production methods, in particular with regard to food, as well as the reorganization of labor, has been identified as a key sustainability challenge. The growing availability of electricity and lighting throughout the twentieth century produced conditions for a '24-h society' that never sleeps, thus decoupling human activities from naturally occurring diurnal cycles and increasing society's ecological footprint in the process. A shift toward renewable energy sources, which is frequently advocated as part of a sustainability transition, is unlikely to reverse this disconnect between societal and natural rhythms.

Sociopolitical and cultural transformations and parallel changes in infrastructure and systems of provision that facilitate individualized activities, as opposed to collectively shared ones, have initiated the desynchronization of human activities and associated rises in resource consumption. Automobility afforded by pro-car policies, the construction of road networks, the availability of (relatively) cheap car and fossil fuels, and the acquisition of driving skills by a large proportion of the population serves as a prime example. Even though the amount of time spent on mobility has changed relatively little over the past 100 years, the level and quality of people's 'consumption of distance' has increased significantly due to the availability of technology such as cars and planes and associated infrastructure (Rau, 2014). Moreover, expectations regarding how much or how little time people are prepared to spend traveling have been transformed in the process, with commuting being seen as 'normal' by many today. The resulting implications for the environment are enormous, with the transport sector consistently featuring among the top three greenhouse gas emitters globally.

That said, the individualization of time use and resource consumption is neither inevitable nor all-encompassing. As Higginson et al. (2013) were able to show, the persistent concomitance of particular activities (e.g., making tea, watching TV, cooking dinner) and associated peaks and troughs in energy demand in UK households present significant barriers to time-shifting demand for energy to match more volatile supply from renewables such as wind energy. While this may be seen as 'bad news' by those who advocate a flexibilization of energy demand in response to the volatility of renewable energy supplies, the apparent persistence of these collectively shared and synchronized time use patterns could play an equally significant role in sustainability transitions if their ecological footprint was to be radically reduced. In other words, the modification of existing mainstream time use practices could fruitfully complement the introduction and mainstreaming of less resource-intensive niche activities frequently associated in the literature with sustainability transitions.

Systematic efforts to theorize and conceptualize the role of time in society–nature interactions remain the exception (cf Rau et al., 2014). Nevertheless, the significance of time use patterns for both the organization of human society and its interactions with the biophysical environment has increasingly been recognized, especially in the field of interdisciplinary sustainability research. Marina Fischer-Kowalski's seminal social-ecological analysis of the relationship between productive work, societal metabolism, and (un)sustainable development points toward the significance of a temporal reorganization of societies for their material resource base (e.g., Fischer-Kowalski and Schaffartzik, 2008). Other authors have identified inherent conflicts between natural and cultural time regimes, pointing to the longevity of nuclear waste beyond the human time-scale or the 'unnatural' rhythms of the 24-h society (Adam, 1996, 1998; Adam et al., 1997). Yet others emphasize the persistence of forms of entrainment whereby the timing of social processes in modern societies continues to be influenced by naturally occurring cycles. Trentmann's (2009) examination of the impact of extreme weather events such as drought, floods, or heat waves on both 'normal' social practices and shared infrastructural systems offers unique insights into the continuities and discontinuities of society–nature interactions in modern societies.

The extent to which different forms of time use incur different ecological costs presents an interesting sustainability challenge. What work and leisure activities require the most energy, water, food, or mobility? In this context, time use patterns associated with particular lifestyles have been shown to be more resource-intensive than others. For example, the ecological footprint of an executive from a Western industrialized country whose work involves numerous long-haul flights per annum, who consumes mostly processed foods, and who engages in resource-intensive leisure pursuits contrasts with that of a small-scale farmer in a developing country who spends most of his/her time to grow food for himself/herself and him/her family and whose everyday life is closely linked to the locality. In addition, the global spread of resource-intensive 'Western' lifestyles, which almost always coincides with adjustments in how people view and use time, has increased resource consumption in areas such as transport and energy. Finally, it has been shown that major life events or 'turning points' in people's biography can impact their consumption patterns in significant ways, clearly demonstrating the need for systematic longitudinal monitoring of time use and resource consumption across the life course (Schäfer et al., 2012; Rau et al., 2014).

To quantify time-use-related differences in ecological footprint has proven to be challenging, although some progress has been made of late. For example, Jalas' (2002) study of two-person households in Finland offers an interesting example of the opportunities and challenges that arise when measuring the energy intensity of selected domestic activities, including food preparation and consumption, washing and cleaning, reading or watching TV. While Jalas himself recognizes the methodological limitations of his approach such as difficulties demarcating activities and the subsequent allocation of energy demand to each activity, his work nevertheless provided a very important starting point

for empirically connecting time use and resource consumption. Similar efforts have since been made. For example, Druckman et al. (2012) use UK data to explore how 'nonwork' activities such as household chores and leisure pursuits give rise to varying amounts of household carbon emissions. By doing so they establish that leisure activities are generally associated with lower carbon emission than nonleisure activities, a fact that has significant implications for gendered analyses of time use and resource intensity.

On an international scale, the availability of harmonized international time use data sets such as the Multinational Time Use Study (MTUS) based at the Centre for Time Use Research in Oxford (UK) offers new opportunities for linking people's time use and their resource consumption and for comparing temporal-ecological footprints across countries. Improved data availability, for instance, through 'smart' metering of household energy use, can provide important insights. These could be complemented by informed estimates of (in)direct resource impacts of different time use categories, for example, through expert rankings of different activities according to how much energy, water, or mobility they require, or how much waste or greenhouse gas emissions they generate. Finally, in-depth qualitative research that captures the social significance of different time use categories could help identify activities that are more or less open to transformation. The relevance of such research efforts for the development of sustainability policies cannot be overestimated.

There is considerable evidence that people's working time has decreased since the Industrial Revolution, which can be attributed to time-saving technologies as well as successful political campaigns for a reduction in working hours and greater regulation of working time. However, measurable reductions in average working hours frequently contradict perceptions of growing time pressure across many societies. In this context, the intensification of time use through multitasking deserves attention as a potential source of stress and harriedness (Shove et al., 2009). Claims that people's days have 40 hours or more if all parallel activities are taken into account demonstrate the significance of what more conventional time use studies label as secondary or tertiary activities. Importantly, these additional activities also incur environmental costs that need to be considered in sustainability assessments of different time use patterns. Is multitasking bad for the environment? This and related questions deserve greater attention in the future.

To summarize, existing work linking time use and resource consumption clearly shows how the social organization of time constitutes an important link between social and natural processes. Greater engagement with the topic of time in social-scientific and interdisciplinary sustainability research, as demonstrated by research discussed in this section, also demonstrates the need to develop alternative theoretical and conceptual approaches that recognize the cultural specificities of human time use both within and across societies.

The Continuous Diversity of Time Cultures

Arguments abound that the worldwide expansion of a modern, clock-based time regime has contributed to the marginalization of alternative time cultures. There is ample evidence of homogenizing influences that impact on the diversity of time cultures today, many of which are associated with the global spread of capitalism and its dependence on economic growth (cf Geißler et al., 2006). For example, Geißler (2002) observes how the spread of a globalized temporal monoculture has drastically reduced time-cultural diversity around the world.

> Modern industrial society has maltreated temporal diversity. It has absorbed and negated it. Time has been mapped monoculturally in line with the abstract measurement of clock time. The aim of this has been to make anything that does not follow unified clock time as compatible with the latter as possible.
>
> Geißler, 2002, p. 132

Interestingly, the taming of human nature through time discipline was part of diverse religious, modernist, and nationalist projects in the past, which frequently included the establishment of powerful institutional time regimes to synchronize social life. For example, attempts by economic and political elites to standardize the measurement and use of time accompanied the establishment of many Western nation-states since the seventeenth century (Zerubavel, 1982; Elias, 1984). Here, Norbert Elias's (1984) work on time and the 'civilizing process' details the gradual internalization of temporal rules set by powerful institutions and elites, including court societies, the church, and the landed gentry.

However, claims of an apparent loss of time-cultural diversity are by no means universally accepted. According to Zerubavel (1997, p. 109), "our standard system of reckoning the time is still not absolutely universal today." There are many alternative time reckoning strategies which continue to coexist worldwide, despite the dominance of Western calendars and clock time. In fact, it is possible to detect a rich tapestry of different time cultures both in more traditional societies that are largely reliant on subsistence farming determined by seasonal cycles and in developed countries whose economies depend on rigorous time-keeping using clocks and Information and Communications Technologies (Rau, 2004, 2014). In fact, most countries harbor significant time-cultural differences. Sociological and anthropological research has revealed a great deal of intranational time-cultural diversity, frequently intersecting with other sociocultural, economic, and material gradients such as class, gender, or rural–urban variations in everyday practices and associated (infrastructural) systems of provision. Moreover, observable changes in time regimes are often context-specific, such as in the case of intraorganizational transformations in working time regimes in a particular company that impact on workers and outside suppliers as well as their families and social networks. For example, Ladner (2009) observes that a strong emphasis on calculating and managing time experienced by employees in the Internet advertising sector significantly influences their domestic lives and that these 'spillovers' from the workplace into the home affect men and women very differently.

Attempts by powerful religious and secular elites to control people's physical environment and standardize their use of time have also remained incomplete because individuals and social

groups have successfully resisted their imposition. Efforts to protect 'nature' and traditional ways of life against the homogenizing pressures exerted by modern capitalism are central to many social movements worldwide, most notably those committed to environmental protection and indigenous rights. Interestingly, the protection of traditional time cultures from modernity has not attracted the same level of collective action, although historical accounts of labor movements in England, Germany, and other countries detail many acts of resistance to the commoditization and calculation of time in the work place (Thompson, 1967). Deliberate efforts to protect this time-cultural diversity such as the *Society for the Slowing Down of Time* (*Verein zur Verzögerung der Zeit)* established in 1990 in Austria remain the exception, partly because the taken-for-granted nature of many time cultures appears to complicate their protection. (http://www.zeitverein.com/framesets/fs_zeitverein.html (last accessed 08.12.13.).) That said, the increasing urgency of many contemporary social-ecological problems has sparked a new wave of interest in alternative and potentially more sustainable time cultures, albeit largely on the margins of the sustainability debate.

The extent to which the diversity of time cultures is under threat because of economic globalization and associated forms of cultural homogenization is unknown. There is ample evidence that a rich diversity of time cultures persists in both (semi-)traditional or modern societies. On the other hand, many alternatives to clock-time thinking and the quantification of time have come under significant pressure. UNESCO's efforts to protect intangible forms of cultural heritage, including cooking rituals and festivals, clearly point toward the possibilities and challenges of sustaining time-cultural diversity into the future.

That said, possibilities exist for protecting socially and environmentally beneficial time cultures against the pressures of a rapidly expanding economic system based on accelerating flows of goods, money, ideas, and people. Using qualitative scenario building, recent sustainable consumption research identified promising practices that require a more or less radical reallocation of temporal and material resources and that could be rolled out within households or organizations. For example, the Spaces for Sustainable Eating scenario for 2050 that emerged from CONSENSUS research envisages more time to engage in cooking, growing food, and eating together, partly because of a reduction and flexibilization of working time (www.consensus.ie; cf Davies et al., 2014 for details of all visioning and backcasting work carried out as part of CONSENSUS). In fact, the growing application of visioning and backcasting techniques in sustainability research and practice, including urban planning and local energy transitions, presents opportunities for refocusing people's time horizon toward the future. Importantly, this type of work demonstrates the need for a long-term approach to sustainability problems that lack an immediate and clear solution, including the transformation of resource-intensive time use patterns in households and organizations and associated shifts in time culture.

Finally, time-cultural differences influence shared understandings of what constitutes a sustainable society and how to achieve it, although this is often not sufficiently recognized (Rau and Edmondson, 2013). For example, variations in time culture relating to how (much) people plan and what pace of life they prefer are likely to shape their sustainability thinking and practice. Are time cultures that embrace long-term planning and distal goals more likely to make the transition to sustainability? Will fast-paced societies find it more difficult to 'slow down' to reduce their ecological footprint and enhance people's quality of life? An in-depth understanding of variations in time cultures between countries, regions, or communities is crucial to their respective sustainability efforts.

Proposals for a Transformation of Time Cultures toward Greater Sustainability

Given that time represents a central aspect of sustainability thinking and practice, it seems little surprising that both theoretical debates regarding sustainability and proposals for concrete measures to promote greater sustainability have covered the topic of time, albeit not always with sufficient depth and rigor. Most definitions of sustainability advocate a long-term approach to development that involves the fair, just, and viable distribution of material resources and opportunities for human flourishing both within *and* across generations. According to Hueting and Reijnders (1998, p. 139), "[t]he notion of sustainability has a long intellectual history, going back to the concept of a 'stationary' or 'steady state' economy employed by nineteenth-century economists […] preference for intergenerational equity has always remained a core element of the concept." Many mainstream indicators of (sustainable) human development also incorporate time-related elements, including life expectancy (cf Rau and Edmondson, 2013).

Claims that a sustainability transition will require a radical transformation of existing time culture which may or may not be compatible with existing systems of time-space regulation have gained momentum. For example, key contributors to sustainable consumption debates have argued for fundamental shift in how individuals, households, and societies view and use time (e.g., Jackson, 2009; Schor, 2010). Juliet Schor (2010) advocates major changes in the allocation of time to address today's pressing social and ecological problems. This also implies a radical shift in how individuals and households produce and consume goods and services. In her view, 'true wealth' depends on the diversification of economic activity and a move away from 'business-as-usual' (BAU) markets and their temporal structures. She observes the emergence of a new social stratum of 'pioneers' whose microlevel activities are geared toward 'plenitude' rather than increased material prosperity. Schor's vision of an alternative social order based on a radical reallocation of temporal *and* material resources by individual actors clearly differs from existing models of (time) poverty and wealth that call for collective action to change the material conditions in society. Instead she advocates a shift toward 'true materialism' that recognizes the environmental costs of production and consumption.

Similarly, Tim Jackson (2009) advocates a redefining of prosperity that embraces human flourishing within ecological limits and that challenges the current uncritical acceptance of economic growth as engine of human development. Importantly, he criticizes inherently unsustainable consumption and spending habits of individuals, organizations, and governments

that result from people's preferences for goods and actions purely because of their novelty, or newness. "[…T]wo interrelated features of modern economic life […] drive the growth dynamic: the production and consumption of novelty" (Jackson, 2009, p. 9). This overemphasis on novelty and its association with human and societal progress has amplified the use of materials and the production of pollution and waste, thus gradually undermining the foundations of human existence on earth. Efforts to stop human-induced climate change and to address other pressing ecological problems thus require a fundamental change in people's time-cultural values and practices that challenge the uncritical acceptance of novelty as inherently positive.

Interestingly, existing efforts to tackle the social and ecological (un)sustainability of consumerism and 'throwaway thinking' in many capitalist societies have focused on the potential (re)introduction of time-cultural alternatives that incorporate both novel and traditional time-related values such as an appreciation of slowness, durability, and 'things that last,' alongside greater recognition of the intrinsically social nature of time and its important synchronizing effects on society (e.g., Grober, 2002). Countercultural forms of resistance to the perceived acceleration and intensification of social and economic life in late modern societies, including the Slow Food movement, newly emerging forms of association that focus on recycling and repairing, or groups engaged in explicitly slow leisure pursuits such as walking, deserve particular attention in this context. It remains to be seen whether or not these niche practices will become mainstream and potentially displace existing 'fast' practices as part of a society-wide sustainability transition. Given that the modernization of many societies has coincided with a largely uncritical rejection of slower, more traditional ways of life as outdated and backward, the future success of initiatives to slow down everyday life is by no means guaranteed.

The threat of accelerating climate change has drawn renewed attention to socially and ecologically unsustainable everyday practices such as long-distance, car-dependent commuting. Proposed solutions include calls for a radical transformation of how people view and use time, focusing in particular on reductions in working hours (and resulting spending power) and an expansion of unpaid activities that enhance people's relationships and well-being. Recent prominent proposals for an overall reduction in working hours (Schor, 2010) or a 21-hour working week (Coote et al., 2010) reflect this debate.

Proposals for a radical reduction in working hours cannot be viewed in isolation from related debates on the causes and consequences of (un)sustainable consumption. The question as to whether current consumption levels need to be drastically reduced (=degrowth) or whether a change in the quality of consumption (='greening' of existing practices) is sufficient to reign in socially and ecologically harmful forms of (over) consumption remains a key focal point of sustainable consumption debates. Many contributors to this expanding field have acknowledged the inherently social nature of everyday practices such as cooking, eating, and traveling and have connected consumption to socially negotiated notions of 'the good life' (e.g., Jackson, 2009; Shove, 2010; Davies et al., 2014). Others have cautioned against business-as-usual approaches that promise continued economic growth through a change in the quality of consumption. For them, calls to consume differently (rather than not to consume at all) simply prolong rather than fundamentally challenge the dominant growth-based economic system that threatens the social and biophysical foundations of human life (e.g., Latouche, 2010; Murphy and Kirby, 2013).

Recent critical debates regarding the relationship between consumption, development, and quality of life have also provided opportunities for exploring more or less radical alternatives to current growth-based models of production and consumption and associated views and uses of time. For example, some authors have put forward very convincing arguments, complemented by detailed empirical evidence, that consumption beyond a certain level does not significantly enhance people's quality of life (e.g., Jackson, 2009; Wilkinson and Pickett, 2010). Yet others see the current economic crisis in Europe and beyond as an opportunity to "imagine a very different future and establish an 'ecological or ethical socialist model,' with less focus on (quantitative) growth and consumption, and more focus on (qualitative) living well" (Murphy and Kirby, 2013). Interestingly, many of these calls for a greater focus on quality of life imply a more or less radical transformation of people's time culture, although this is not always made explicit by their advocates. Moreover, there is currently little evidence of a fundamental shift in thinking away from quantitative growth and toward qualitative changes in how societies organize themselves and their economies, including people's time-related views and practices. Instead, many countries in the European Union and beyond have concentrated on efforts to return to pre-recession levels of economic growth. Existing proposals for a more sustainable, quality of life focused use of time as part of a concerted challenge to the prevailing growth logic have not yet received the level of recognition they require to be successfully implemented on a larger scale.

Arguments that a deceleration of everyday life forms an essential part of any sustainability transition have also not been without their critics. At the conceptual level, Shove et al. (2009) challenge simplistic fast/slow dichotomies of time use and narrow causal models that attribute the modern 'time problem' solely to the work-and-spend logic of consumerism. They also critique concepts of time as a resource that can be easily quantified, stored, released, and used up. Instead, these authors argue for a more nuanced analysis of the complexity of everyday temporal practices, emphasizing the creative (re) production and consumption of multiple temporalities (Shove et al., (2009), p. 3).

Jalas (2002) draws attention to the possibility of time rebound effects whereby time that has been freed up due to efficiency gains may be filled with new and potentially more resource-intensive activities. For example, a reduction in working hours would most likely increase rather than reduce people's ecological footprint if time poverty (rather than financial constraints) had prevented their engagement in resource-intensive acts of consumption in the past. This clearly challenges more simplistic 'time equals money' views of human time use and associated resource consumption. Whether or not a reduction in working hours will increase or reduce people's ecological footprint thus depends on what types of activities people adopt *in lieu* of these working hours.

Conclusions and Outlook

Changes in the temporal fabric of society, including the acceleration of production and consumption, have intensified the use of natural resources to an unsustainable level. This has sparked debates about an alternative future for people and the planet that reconciles economic development with social justice and ecological integrity and that promotes the adoption of new temporal practices that work *with* nature rather than against it. Arguments for a radical shift in time culture away from short-termism and toward a long-term perspective that recognizes the needs of future generations are central to recent sustainability debates. Similarly, calls abound for a shift in the allocation of temporal resources, including a reduction in working hours, an improved work-life balance, and a general deceleration of everyday life. However, many of these proposals tend to remain too focused on measurable aspects of (working) time. While these time-related changes have the potential to transform how people live and work, they are unlikely to suffice in reversing current trends in material consumption, emissions, and waste, partly because of emerging time rebound effects. What is instead required is a critical examination of qualitative changes in people's time culture that has accompanied the transition to late capitalism, culminating in unsustainably high levels of consumption. Their potential to systematically undermine alternative sociocultural practices that adopt a long-term, intergenerational perspective and that are less resource-intensive as a result deserves particular attention. Overall, the necessity to take time seriously presents a major challenge for future sustainability research and practice, with promising starting points already in place.

Time Use Research Methods

Jonathan Gershuny, Nuffield College, University of Oxford, Oxford, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Individuals' time use is a key social indicator, directly reflecting both production and consumption as well as embodied capital investment. Various methods are used to measure time use, of which the time-use diary sample study is the most widely used. Time-diary survey methods vary widely both in design and mode of administration, though all instruments have in common a requirement of complete and continuous registration of activities of sample members on designated days. This article discusses the range of design options, and as well as major studies conducted over the last 50 years.

Why Study Time Allocation?

We all have 1440 min in our days. While we can buy goods, and the services of other people, we cannot directly purchase more minutes for ourselves. However, *as* we buy goods and services, and sell our own labor, we are trading our own time, and other people's. Furthermore our position in this market for time reflects aspects of our own past histories – how much time we spent in interaction with pa and siblings in our households of origin, how much time in schools and training and in various sorts of work and leisure activities. The work experience accumulates through the life-course to form that aspect of human capital that determines prospective earnings rates. Those whose hourly wage is greater than the average may wish to sell a relatively large part of their day as paid labor, since their earnings can, in effect, buy a still larger amount of time indirectly, as embodied in goods and services.

So the apparently equally distributed resource, is, paradoxically, both a source of, and a fundamental expression of, social differentiation. How we spent our time in the past accumulates to provide the embodied social, cultural and economic capitals (or capabilities) that help to determine our current time allocation, and not just between work and leisure, but also, through mechanisms set out by Becker (1965) and Bourdieu (1985), among different sorts of paid work and of leisure consumption. And employment-related human (or economic) capital is in effect a mechanism for redistributing time, giving individuals differential levels of effective control over time, either below or above the 1440 min of the day.

Those whose expected earnings rates are below the a society's average wage (and who have no financial capital) *must necessarily* exchange each hour of their paid work for goods and services that embody on average *less than* an hour of the work of others. Those with higher wage rates may exchange multiple hours of embodied labor for each hour of their own work. Once we subtract paid work time from individuals' days, and add back the time embodied in purchased goods and services, the poorer members of a modern developed society (with lower levels of embodied human capital) might effectively control only 15 or fewer hours each day, while the richer members (those with higher human capital) might control 50 h or more per day.

Yet despite this crucial role in the emergence of social structure, time allocation evidence does not at present form part of the core research material of any social science discipline. Why?

One contributing explanation is the paucity of adequate individual-level time-use data. We have limited knowledge of our own time use. Like fish in water, we live in time; we are *in* it, but not aware *of* it. As a consequence, we are not well equipped to mark its passage or duration and in any case, the social scientist is interested not in time itself but in the particular activities to which successive periods are devoted. So, for example, if we ask survey respondents directly how much time they devote to a particular activity over a given period, the answers we get reflect little more than conventional expectations ("I work 40 h per week" our respondent may tell us, because her employment contract states this – but her *actual* hours worked are only accurately known if there is some externally imposed mechanism for registering this). For many categories of activity (housework, leisure activities, travel, etc.) respondents are unable to provide any straightforward answers at all (unless they report complete nonparticipation). There is no particular reason why we should need to know such an abstraction as the amount of time devoted to each element in a general classification of activities in the course of daily living; so we cannot always give accurate answers to researchers when they ask us about them.

Methodological Alternatives

There are four distinct approaches to the measurement of time use in a population: 'stylized estimates' as part of questionnaire enquiries, *observational methods*, using *administrative records*, and *diary methods*.

Despite the fact that people are often unaware of their time allocation, much of what currently passes for scientific knowledge of time allocation nevertheless relies on direct questions to survey respondents. In particular, the standard models for the Labor Force Surveys collected by most developed countries routinely ask for estimates of amounts of time, on average, or over a typical week, or during the previous week, spent working in paid employment. Other surveys ask similar questions about time devoted to, for example, childcare and domestic chores. These produce 'stylized estimate' measures of time use.

This approach is the simplest and cheapest way to collect information about how people use their time, but it has

significant drawbacks. Research on the paid work time estimates deriving from this methodology suggests substantial and systematic biases (e.g., Robinson et al. 2011). Those who claim to work in excess of 40 h per week progressively overstate the length of their work-week. The reason for this bias seems to be that as work time increases it becomes more difficult to accommodate other necessary or desirable activities outside scheduled work times. The longer the actual work time, the more likely it becomes that activities that might otherwise be located in 'free' time (e.g., medical visits, shopping, sports participation) are inserted at times that the respondent normally expects to be at work, and hence the greater the proportional overestimate. These exceptional events between conventional work-start and -finish times are often forgotten, whereas the exceptional events that lengthen the working week (e.g., overtime) are more likely to be remembered in the context of a question about paid work time.

Ethnographic research has often involved direct observation of people and the recording of their activities by researchers. New technology now extends the role of direct observation, including such unobtrusive devices as individual location monitoring systems and closed-circuit or internet camera systems.

Observational methods have certain advantages, in that the researcher can ensure that respondents do not forget or suppress particular activities of interest. In the case of new technology, the option of reviewing audio tapes and video images can ensure accurate recording of people's activities; ambiguities can be reassessed until a maximally precise determination can be reached. Such methods may be useful for analyzing small samples of special groups (e.g., residents of a retirement home or a small rural community) or activities in a specific location (such as the numbers of people who pass by a shop display and react or who engage in various activities in a town center).

On the other hand, direct observation studies are costly, they are generally labor-intensive, and they may compromise personal privacy. Moreover, people can be expected to censor or change their normal patterns when they are aware of continuous monitoring (the more so if they are conscious of an observer of differing nationality, class, sex, ethnicity, age group, or religion). However, continuous monitoring of behavior via continuous recording of position using GPS, physical activity using accelerometers, and individuals' visual fields via continuously recording cameras worn on clothing or as headgear, are gaining acceptability. And some extension of these methods, perhaps in conjunction with 'beeper' techniques (more formally 'experience sample methods' or ESM, used for example in a 2010–11 add-on module to the annual American Time Use Survey) allow respondents to record affective responses to current activities on random occasions during the day.

But, for cost and other reasons, notably the low and highly selective samples resulting from the intrusive and demanding nature of these methods, these approaches are not at present widely used to provide representative evidence of societies' time-use patterns.

Less direct observational methods ('unobtrusive measures') are becoming increasingly prevalent. These include programs tracking the use made of computers at work and school (measuring the time people spend word processing, performing data analysis, checking e-mail, browsing the web, and so forth), phone call and retail transaction records and the like, recording what people do at particular times and in particular places.

Administrative records, some of which cover considerable periods of time, chiefly concern the official records of hours during which people are in engaged within institutions. Most typically, this involves employers' records of employees' work hours, but it could in principle now involve any of those recreational facilities, hospitals, prisons that use electronic methods to monitor individuals' entries and exits. Administrative records typically provide large numbers of cases for analysis. However, they only cover the population which has contact with the institutions keeping the records, and do not indicate if people have simultaneous contact with related institutions at the same time (e.g., working in two jobs). They tend to contain a bias against short spells, and the contextual information about personal and socioeconomic characteristics typically needed for academic or policy research is sparse.

Many of the problems with the foregoing methods are solved if respondents are asked to provide a complete account of the sequence of events, during one or more days, within a framework of clock-times. This 'diary' approach, unlike the stylized estimate method, involves a narrative skill that is often called for in the course of daily life. Diary methods are by far the most widely used techniques for the estimation of time-use patterns: There are at least 500 such studies, from at least 80 countries. Approximately half of these countries can provide at least one full national random sample of diary-based time-use evidence.

Diary Methods

The diary method provides a number of clear advantages, which stem from the fact that the narratives mirror, in a straightforward way, the structure of people's daily activities. Diaries require the respondent to engage in an active process of recall, in which they reconstruct the successive events of the day, so that the particular occurrences (such as a trip to the doctor that disturbs the normal passage of the working day) emerge naturally as the respondent recollects 'what happened next.' Diary accounts are complete and continuous, so any respondent intending to suppress some activity must make a conscious effort to substitute some other activity. This will also tend to limit exaggeration of the duration of particular activities, since the potential for double counting (e.g., of a period as both work and leisure) that is entirely possible using the stylized estimates, is precluded in diary accounts. There are other advantages for the analyst in the diary-reporting format. Increasingly researchers are interested in investigating the activity sequences themselves, or the times of the day at which activities occur; simultaneous activities can be properly investigated, and if multiple diaries are collected within a single household, researchers can use them to investigate patterns of copresence, interdependence and cooperation.

The time-diary method itself is nevertheless not unproblematic. In particular, it produces some "under-reporting of socially undesirable, embarrassing, and sensitive" behaviors,

including personal hygiene, sexual acts, and bathing (Robinson and Godbey, 1997: 115). Techniques for persuading people to account completely for their days need some refinement.

Diary Data Collection

There is wide variation in the design of time-use diaries. The summary results seem quite stable with respect to the different methods, and comparisons of different methodologies do not suggest any unequivocally dominant methodological choices (although Harvey, 1999 provides general purpose recommendations). Choices are problematic (cost issues apart) because particular design characteristics affect respondent burden and hence response rates. There is a straightforward trade-off between a 'heavy' design, which yields a fuller picture of individuals' activities but relatively low response, or a 'light' design providing a less detailed picture, but with a higher response rate.

For example, diaries may cover longer or shorter periods. The problem, which is unusual in survey research terms insofar as most personal characteristics are fixed at any historical point, is that individuals' activities differ from day to day. Suppose all respondents do a weekly clothes wash on one randomly chosen day of the week: a single day diary will suggest that one-seventh of the sample spend a lot of time in laundry and six-sevenths do none, where the reality is that all do, on average, a small amount. A short diary gives a spurious impression of interpersonal variability which is in fact wholly intrapersonal. A week-long or even multiple-day diary would reveal the real situation, but is of course very demanding for respondents.

There are two alternative modes of diary administration, conventionally referred to as 'yesterday' and 'tomorrow' studies, the former involving an interviewer-led and recorded process, the latter, a self-completion instrument. The 'yesterday' diary normally does cover the previous day, as recall of events decays quite rapidly, but it is practicable to collect useable information after a gap of 2 or even 3 days, and difficulties in recruiting respondents over the weekend may mean that this is necessary so as to ensure even coverage of the days of the week. The interviewer leaves the 'tomorrow' self-completion diary with the respondent with the instruction to make records as frequently as possible through the diary period so as to maximize the recall quality. Tomorrow diaries have normally covered either 1 or 2 days, but experience in the Netherlands and the UK shows that periods up to a full week are possible, though with reduced response rates.

A variety of interview technologies have been employed for yesterday diaries. In addition to conventional pen and paper personal interviews, there are examples of computer-aided personal interviews (CAPI) and computer aided telephone interview (CATI) methods. Studies sometimes use a combination of yesterday and tomorrow diaries with the self-completion instrument being posted back by the respondent. In this case the tomorrow diary shows lower and somewhat biased responses. For tomorrow diaries, response is substantially improved if the interviewer returns to collect it.

A second substantial design issue concerns the temporal framework within which the activities are recorded. A key decision here is whether to adopt an 'event' basis of recording: 'When did you wake up?,' 'What did you do first?,' 'When did you stop?,' 'What did you do next?' This style is appropriate for a 'yesterday' interview, but not for a tomorrow diary. For self-recording, it is more appropriate to use a schedule with regular time slots, of 5–15 min (although slots of up to 30 min have been used, and the length of the slots may vary through the day and night). With this approach, respondents indicate the duration of each activity on the schedule using lines, arrows or ditto marks.

Activities may be reported using either a 'closed' vocabulary, in which a predetermined set of activity codes is provided to cover the full range of possibilities, or an 'open' approach in which respondents use their own words to describe the activities, these being coded subsequently. Respondents often report that they find the 'closed' approach constraining, however well-designed the categories, and the choice of categories may, to a limited degree, influence the level of reporting (e.g., a more detailed classification of travel types leads to a small increase in estimates of travel time). But the open approach has symmetrical shortcomings: respondents report at varying levels of detail, which are difficult to disentangle from genuine interpersonal differences.

For much of the day it is difficult to classify the current state as a single activity. For example, 'writing at the computer' may be accompanied by 'drinking coffee' or 'talking to my child.' The normal practice is to ask respondents to record activities in a hierarchical manner: What are/were you doing? Were you doing anything else at the same time? Some studies ask respondents to record all activities in a nonhierarchical manner, but respondents tend to prefer the opportunity to use a narrative mode ("First I did this, and then I did that …") which provides a hierarchy of primary and secondary activities. The hierarchy also simplifies the process of analysis, though there are ways of analyzing the data that are nonhierarchical but still conserve the 1440 min of the day.

Other ancillary information included within the rows or columns of diary forms include variables such as: 'Who else is present/engaged in the activity?' and 'Where are you?' (the latter often requesting information on modes of transport). National income accountants' interest in nonmonetized economic activity has led to attempts to acquire 'Who for?' information, but these have not so far been successful. Specialized diary studies also include interpretative or affective information (e.g., 'Is this work?' or 'How much did you enjoy this?') attached to each event or activity.

Beyond the design of the diary instrument, there are also various specialized sampling issues. Seasonal effects may be of importance; representative samples of time use require an even coverage across the year. There are serious practical difficulties but most national-scale samples attempt multiple sweeps at different parts of the year. The most developed approach to temporal sample design is found in Poland, whose 1970s and 1980s studies achieved approximately even numbers of diaries for each *day* of the year. Samples that include simultaneous diaries for all household members greatly extend the analytical usefulness of the evidence. Conventional 'tomorrow' studies include children from the ages of eight and Italian national studies have, by a combination of simplified forms for younger children, and parental proxies for preliterate children, achieved total household coverage.

Time-Diary Research Studies

Large-scale national random sample studies have been conducted in each of three or more decades in more than 20 countries. The first cross-national comparative time-diary study was supported by United Nations Educational, Scientific and Cultural Organization (UNESCO) in 1965 (Szalai, 1972). Gershuny (2003) reports on diary studies from showing 16 countries' historically changing time-use patterns. Seventeen countries participated in Eurostat's 1996–2004 European Harmonised Time Use Study (HETUS) project, and a new tranche of HETUS studies (covering 2008–15) is currently in the field. Results from the Multinational Time Use Study, providing evidence of change in time use over the period 1961–2010 from 23 countries, are reported by Fisher and Robinson (2011). And an increasing number of Pacific Rim, Developing and Less Developed Countries are now collecting time-diary studies.

Time Use Research: Recent Developments

John P Robinson, University of Maryland, College Park, MD, USA
Teresa A Harms, University of Oxford, Oxford, UK

Abstract

Academic and government researchers from most industrialized countries and an increasing number of developing countries are collecting and analyzing full 24-h time-diary data. These diary data provide a comprehensive and accurate basis for generating national accounts of time spent working, sleeping, and spending free time, and how daily life varies across demographic groups, across decades and across countries. Diaries can also provide data on multitasking, interacting with others, and the location and timing of daily activities in the American Time Use Survey and in more than 25 other (mainly European) counties. These diary data are being standardized and archived via the Multinational Time Use Survey at the University of Oxford.

Considerable progress has been made in producing tables of comparative time use in and across these countries and in identifying and visualizing patterns of multinational time use using Multidimensional Scaling. Major attention has been focused on uses of time in families, with special attention to the implications for our understanding of the division of paid and unpaid work within households. Given the richness of diary data available, less attention is now given to trends from time-estimate questions, although brief mention is made here to useful estimates from the US General Social Survey on important free-time activities and subjective time measures.

In order to provide greater insight into the sociological meaning of these activities for national accounts, supplemental data have also been collected on subjective and qualitative characteristics of diary activities, such as enjoyment, stress, and outcomes. Both in the United States and other countries, diarists generally rate activities related to social life, religion, and interactive childcare higher in enjoyment, and activities related to household upkeep and health care at the bottom. In more recent surveys, paid work activities and TV have received less positive ratings. Furthermore, recent US surveys indicate no increase in time pressure, a subjective factor that has been consistently related to lower life satisfaction. Fuller coverage of these ratings is covered in a separate entry in this volume titled Subjective Time.

Introduction

Time figures prominently in the structure and quality of people's lives. Sociologically, time-use research focuses on the lives of individuals – usually in the form of self-reports from nationally representative samples – a simple documentation and accounting of the hours and minutes spent on various daily activities, like paid work, TV viewing, and time alone. Time use has become prominent as more government agencies conduct time-diary surveys, particularly with the creation of the American Time Use Survey (ATUS), described below.

Impressive advances have been made as well in measuring *subjective time* (covered in more detail in a separate article) using surveys in questions that ask people how they perceive their time use and how they feel about and value the way they spend their time. Simple diary figures by themselves generally do not have immediate quality-of-life (QOL) implications, in that survey analysts cannot assume that a person's QOL would rise or fall as they spent more time eating or traveling. In contrast, analysts generally seem more ready to draw such QOL implications when parents spend more time with their children or when people have more available free time.

Infrastructural Developments

The main two diary data sources to available researchers studying time use are the Multinational Time Use Survey (MTUS) for multinational data and the ATUS for US data. Both are multiyear and national in scope, the MTUS covering from the 1960s to today and the ATUS continually from 2003 to the present.

The MTUS Data Archive

A major stumbling block to comprehensive scientific study of time use has been the wide variety of methods and field procedures used by researchers in different disciplines and different countries to address diverse social issues. This Tower-of-Babel problem had been largely sidestepped in the 1965 pioneering multinational data collection – the multinational time-budget study, as initiated and supervised by the Hungarian mathematician and sociologist, Alexander Szalai (1972). Based on his extensive experience of trying to make sense of the fragmented series of early 'pilot' and historical studies in Eastern Europe, Szalai organized and enforced a strict set of methodological guidelines and procedures in this monumental 12-country effort.

In the ensuing 30 years, diary researchers from a number of countries and disciplines have organized a series of individual advances in diary methods and procedures, but their successes were undermined by a failure to achieve comparability across countries and even studies within countries. This disparity was formally recognized and addressed by the efforts of EUROSTAT's Harmonised Time Use Study (HETUS) in the 1990s. However, there remained the tedious tasks of standardizing, documenting, and disseminating these data.

The Oxford Centre for Time Use Research (CTUR) has created a standardized data archive from both the HETUS, and other disparate individual country diary studies (Fisher and Gershuny, 2014). Their harmonized data files are now available to social science scholars around the world. The MTUS Web site contains complete data files for a rapidly growing group of studies from more than 20 countries (some dating back to the 1960s). It also houses the American Heritage Time Use Study (AHTUS), a complete standardized formatting of all US diary studies dating back to 1965, with diary codes and background variables harmonized for comparability across time and including the ambitious diary collection in the ATUS described next. CTUR also produces a number of valuable resources including newsletters identifying the latest studies, publications, and conferences of interest.

An illustration of the value of the MTUS archive is shown in Table 1, as compiled by Fisher and Robinson (2011). It summarizes, in a simple single comparative table, the contrasting time use patterns across 23 countries around the world to identify the major similarities and differences in daily life between 1998 and 2005. An example of how the complex set of relations in Table 1 can be simplified even further and distilled into a plausible two-dimensional map, is shown in Figure 1 below.

CTUR's role in the MTUS is now supported over the period 2014–19 by a grant from the UK Economic and Social Research Council. This funding will allow the Center to update the UK studies of diary trends; innovate new diary methods involving the Web and smart phone applications, as well as deploy monitoring devices such as GPS, wearable cameras, and accelerometers; expand studies of subjective time; engage in collaborative diary studies with other HETUS countries; and recruit and train new generations of time use scholars from other countries.

The American Time Use Study

The first US national diary study was conducted in 1965 using personal interviewers and was then replicated every decade afterward, in 1975, 1985, 1993–95, and 1998–2001, mainly by telephone. All diaries were collected by academic survey firms, first at the University of Michigan and since 1985 at the University of Maryland. Most of the surveys achieved response rates over 65% and used an activity classification derived from that used in Szalai's pioneering 1965 study.

Since 2003, the US Census Bureau has been collecting ATUS 'yesterday' diary data continuously on behalf of the Bureau of Labor Statistics (BLS). With samples of around 12 000 respondents per year, it now has a cumulative sample base of more than 140 000 respondents aged 15 years and older. Respondents are selected from the US Census Bureau's Current Population Survey (CPS) and are interviewed by telephone (after the 8th CPS wave). The ATUS maintains a response rate of about 55% of CPS respondents. Despite this relatively low-response rate for a Census Bureau survey, Abraham et al. (2006) present considerable evidence that the ATUS sample remains representative of the US population.

The ATUS has an unusually long list of diary activity categories, but more than 400 entries are not directly comparable to the Szalai-derived schema used in previous US academic diary surveys. The detailed set of ATUS activity categories are described at www.bls/tus.gov and the data are archived for direct access at www.atus-x. A condensed list of 25 summary activities is shown in Table 2. The ATUS has also enhanced the interpretability the diary records with new modules of questions related to eating and health and subjective well-being, discussed in more detail in various sections below. In its AHTUS standardized archive, the CTUR has generated a single harmonized set of data files that merge the early surveys with the more recent ATUS file.

Table 2 presents a trend summary of ATUS results for each year in the decade since 2003 for the total US population aged 15+, as reported in BLS news releases (Robinson, 2013c). It can be seen that the activity totals are remarkably consistent across years. This is particularly surprising because in 2007, the US underwent its most serious economic recession since the 1930s. Yet, as Table 2 shows, there was only a 1 h (3%) overall decline in work-related hours in the ATUS across the decade (or 1.6 h from its high of 26.3 h in 2006). Table 2 also shows that the ATUS recorded a decrease of almost an hour per week in care given to nonhousehold members (which could signal a serious hole in the nation's social 'safety net'). thus decreases were offset mainly by a 1.5 h increase in sleep and 1.7 h increase in TV viewing, two activities that have been strongly linked to decreased work hours.

Unexpectedly, there was less than an hour of extra time spent with new information technologies (IT), a decade so obviously marked by their rapid diffusion. However, a major problem in measuring IT use in the ATUS data is that IT use for other noncommunication functions (like shopping and games) are counted as time for those activities, rather than for communication. Similarly, low weekly hours of IT use were found in time diaries from other Western countries (Robinson, 2011). Again, cross-national comparisons with US IT usage is complicated by the different activity coding schemes employed. However, the continuous annual nature of the ATUS data compares favorably with the 5–10-year intervals for the other national data series in the MTUS.

Visualization Maps of International Activity Differences

Time diaries contain a wealth of data on almost every facet of everyday life, and the detailed breakouts of more than the simple disaggregation of 400+ activities by demographic variables can generate thousands of relevant data tables, which may become unmanageable for time use researchers. Factor analysis and related tools are useful methods of data reduction in the social sciences more generally. But the single-day data collection period common in time-diary studies is too short to reveal meaningful within-country patterns of activity correlations for factor analytic purposes.

However, one of the notable methodological innovations that became available to social scientists during the 1960s was the multivariate data-reduction technique of Smallest Space Analysis (SSA) (Guttman, 1968; Kruskal, 1964). Also referred to as multidimensional scaling (MDS), it has become one of the standard analytic tools available in SPSS and other statistical packages (Bloombaum, 1970).

Table 1 Multinational average weekly hours across 23 countries for whole population, 18–64 h (from Fisher, K., Robinson, J., 2011. Daily life in 23 countries. Social Indicators Research 101, 295–304.)

NA: no data available.

Figure 1 MDS Map for 20-country MTUS data.

Among the wide variety of other complex social phenomena that have been reduced to simpler spatial visualizations via SSA include occupations (Laumann and Guttman, 1966), work values (Elizur, 1984), and public perceptual maps of the world (Robinson and Hefner, 1968). The technique has more recently been applied to summarize results from the World Values Survey, using the respondent's agreement with various value statements in different countries. Inglehart and Welzel (2011) have generated a map that reduces these complex responses to a simple two-dimensional space that can be viewed at worldvaluessurvey.org.

MDS Applied to Szalai's (1965) Multinational Data

The multinational time-diary data from the pioneering time-diary study of Szalai (1972) became available soon after the SSA/MDS technique was developed. Converse (1972) applied MDS to a matrix of differences in the daily times spent by people in each country on a range of activities as shown in Table 1. His resulting two-dimensional MDS visualizations provided immediate and plausible insights into how similar life was in the different national settings involved in the study. Converse (1972) succinctly described the resulting MDS diagram as a picture that "bears a substantial resemblance to a map of the western world…It is remarkable that statistical compression of these raw data yields anything resembling a physical map" (p. 150).

Updated 1998–2005 MTUS Mappings

Figure 1 illustrates the application of MDS to the 1994–2005 MTUS time use data in Table 1. Following the same procedures that Converse (1972) employed, a half-matrix of Euclidian distances between the time use patterns in 23 countries between 1998 and 2005 (as calculated directly from Table 1) was used to generate a map representing the major differences between countries, again in a combination of cultural and geographic terms (Robinson and Gershuny, 2013). Again, Figure 1 clearly shows the influence of geography, although now more along language/culture lines than pure geographical proximity – mainly because, unlike the earlier Szalai data set, the widely dispersed Anglophone countries of UK, Canada, and Australia are now included in the survey.

The MDS has also been applied to examine parallel country differences among immigrant groups in the ATUS, which by 2010 included diaries from more than 10 000 immigrant respondents. Table 3 reports the time US immigrants from 26 categories of national origin devoted to various broad time use categories.

Initial analysis showed that the time use of these immigrants did not differ markedly from their US-born counterparts. However, there are still marked origin-country differences within Table 3. Immigrants from India, Africa, and certain Asian and Central American countries spend notably higher averages of time in paid work, for example, while immigrants from Canada and European countries spend less time in paid employment than other immigrants and native-born Americans.

Some of these country-of-origin differences are suggestive of more general regional or cultural patterns. Time spent in housework, for example, is higher among migrants from western European countries and lower from eastern European countries. Sleep time is higher among immigrants from Latin American countries compared with Japan and Korea. IT use is higher among Asian and eastern European immigrants and lower among those from Latin American countries. Clearly, it is almost impossible to comprehensively summarize these differences shown in the 664 entries in Table 3 in a few sentences or paragraphs. When subjected to an MDS analysis, however, Figure 2 again captures the distinct cultural and geographic patterns that separate the activity differences among immigrant groups in the United States.

Among US residents with different countries of origin, US-born citizens lie almost in the center of its two dimensional mapping, with Latin American origin countries generally to the 'south' of the United States, Asian countries generally to the 'east' and European countries to the 'north.' African and Indian immigrants cluster to the 'south' and 'east' of the United States, about equidistant from Asian and Latin countries. Russian and eastern European migrants appear closer to Asians than to other Europeans, and closer to south American (mainly from Brazil and Argentina), who are rather distant from other Latin countries. The closest lifestyles to the US-born citizens are from former residents of the Philippines and Japan.

Trends and Patterns in Specific Activities

Paid Work

The availability of long-term historical comparative time use materials produces dramatic research findings. Gershuny (2009) reported a 'Veblen in Reverse' trend. Members of the 'dominant' class at the end of the nineteenth century displayed their high status (and wealth) through conspicuous consumption during plentiful free time. By contrast, today's dominant classes spend more time at work, while the earlier 'working' class has fewer hours of paid work. Mestdag and Glorieux (2009) challenged the model of a new global '24/7-economy' by observing no greater proportions of Belgians in paid work across the day than in diary studies in the 1960s.

Unpaid Work

In an influential *Scientific American* article Vanek (1974) suggested that, despite the spread of labor-saving home appliances over previous decades, women's housework had basically not declined since the 1920s. It is now being widely reported that the ensuing 1970s gender revolution, and associated declining housework since these 1970s, has hit a wall, or at least 'stalled.' However, using recent data from the MTUS, Kan et al. (2011) show a striking downward trend in women's share of the unpaid work in the United States, and three other Anglophone countries (Canada, Australia, and the UK) suggesting a regular but slowing shift toward gender equality (Figure 3).

In the United States, for example, women's proportion of unpaid work declined from 77% in 1965 to 62% in 2010 – in both cases a little ahead of the other Anglophone countries. Contrary to the negative view of the US record on gender equality in the workplace, American men in fact carry out a larger share of the unpaid work than do men in other Anglophone states – 38% of the total in 2010 and showing continuing, if slowed, progress toward the 50% point of gender equality. Moreover, they present parallel graphs that show Anglophone countries performing somewhat better than in continental Europe, and *much better* than in southern European countries, but with countries from northern Europe Nordic doing the most (Swedish men at 41%).

This follows the earlier findings of Kan et al. (2011), Bianchi et al. (2006) and Fisher et al. (2006) historical gender convergence in the United States. At the same time, Bianchi et al. (2000) produced tables that showed a leveling off of that trend in the United States since the

Figure 2 MDS map of time use of US immigrant groups.

1990s. Sayer and Bianchi (2004) and Gupta et al. (2009) found important differences in housework times among different ethnic groups in the United States and in Scandinavian countries.

Childcare

Bianchi et al. (2006) found that American mothers and fathers were spending consistently more time with their children and that this trend could be found in other Western countries. This is much as Gauthier et al. (2004) had determined earlier. At the same time, Bianchi et al. (2006) and Milkie et al. (2004) found that US parents *felt* they were spending too little time in childcare, even though their children did not share such feelings. Gauthier et al. (2004) also found parents investing more time in children in selected industrialized countries.

Figure 3 Multinational trends in the gender division of unpaid work.

Shopping and Services

As shown in Table 2, there has been relatively small change in the weekly hours US women (6 h) and men (4 h) spend shopping, which is much the same difference that was found in 1965. This is in marked contrast to the converging trends in the revolutionary changes found for the other two aspects of family care noted above.

Personal Care

Sleep

Contrary to the popular stereotype of the United States and other Western countries as increasingly sleep-deprived, Robinson and Michelson (2010) provided evidence of increases of sleep over the last 40 years in the United States and Canada, as well as other Western countries. Moreover, Michelson (2011) found no support for the argument that 'unhealthy decreases' in sleep patterns resulted from the imposition of daylight savings time in North America. It appears that the ATUS data systematically recorded an hour or more a week more sleep than in earlier studies, possibly related to the 4 a.m. diary starting time.

In terms of the related personal care activity of sex, one that is grossly underreported or disregarded in the ATUS and other time diaries, Robinson (2010) found that less than an estimated hour a week was spent in such activity and that time

had remained quite steady since 1989. Moreover, there was considerable support for the accuracy and consistency of these stylized estimates.

Eating

Substantial use has been made of the new 'eating and health' data, now a regular supplement to the ATUS, in which questions related to Americans' obesity problem were added. Both Janes et al. (2011) and Zick and Stevens (2011) found no direct link between eating time reported in diaries and obesity, although there was evidence relating obesity to less exercising as well as eating as a secondary activity across time. However, Brown et al. (2011) found a strong link between snack eating and obesity (and TV viewing) among Australian teens.

Grooming

Some evidence of decreased grooming time in the ATUS, which may be related to the 'dressing down' movement, can be found in the US diaries.

Free Time

Aguiar and Hurst (2007, 2009) provided evidence that American free time had increased since 1965, much as Robinson and Godbey (1999) reported earlier. However, some reversals have been apparent in the ATUS data since 2006 (see **Table 2**) due to the slight decrease in paid work activity.

Organizations and Volunteering

Abraham et al. (2009) noted how respondents who agreed to complete a time diary for the ATUS reported more volunteering activity in a prior interview than those who did not complete a diary. This is consistent with a view that survey participation is itself a form of volunteering activity.

Social Life

Robinson and Lee (in press) and Robinson (2011) found there were no notable declines in socializing apparent in more recent GSS estimates and ATUS diary times in social life. Gershuny (2003b) reports similar findings.

TV viewing and IT Use

Robinson and Martin (2009) noted no notable declines in TV viewing apparent in more recent MTUS diary times, much as had been reported in earlier studies of Internet impact (DiMaggio et al., 2001).

Differences across Special Demographic Groups

Children's Time Use

Hofferth and Sandberg (2001) and Hofferth (2010) have continued to document important changes in how American children spend their time, as has Raley (2006). Brown et al. (2011) found that higher TV viewing time by school-age children was associated with lower physical activity, higher snack food consumption, and unhealthy weight.

The Child Development Supplement (CDS) of the Panel Study of Income Dynamics (PSID) surveyed over 2500 children through health and achievement test surveys, primary caregiver and child interviews, and a 2-day time use diary (1 week and one weekend day (Hofferth and Sandberg, 2001). Data were collected in 1997, 2002/2003, and 2007/2008 for children in this cohort who remained under 18. The information collected includes a broad array of developmental outcomes including physical health, emotional well-being, intellectual and academic achievement, cognitive ability, social relationships with family and peers, time diaries, and much more.

Hofferth and Sandberg (2001) examined how American children under age 13 spend their time, sources of variation in time use, and associations with achievement and behavior. Their two-day diaries revealed information about the children's time spent in school settings, free play versus organized activities, out-of-school learning activities, and family activities. The data for the analysis were drawn from the 1997 CDS to the PSID.

Seniors

Robinson and Caporaso (2009) found that most differences among retired US seniors centered on fewer active activities, with increases in TV viewing, reading, and relaxing.

Time Changes and New Communication Technologies (IT)

Three early studies of the impact of IT on American society suggested that it was having a negative impact on social life, as well as mass media use. For example, initial findings from Kraut et al. (1998) suggested a negative Internet impact on social life, which was later reversed in Kraut et al. (2002) as more people went online.

However, this was not supported by the results from two large multiyear US national surveys that have been monitoring social change in US daily life with high response rates. These include the 1974–2012 General Social Survey (GSS) with more than 55 000 adult respondents aged 18+ years, which collected time-estimate questions on particular social and media activities, as shown in **Figures 4(**a–c).

As in the ATUS, there seemed little if any evidence of significant impact of IT media on social/media time, even though the GSS showed that IT had already become a predominant source of information and social contact by 2004. **Figure 4(a–c)** shows that GSS respondents in general have not reported lower levels of social or media contact since the 1990s, and while those GSS respondents who spent more time on the Internet reported fewer social visits with relatives, they also reported more visits with friends compared to those who did not use the Internet.

The main difference between users and nonusers in the ATUS was with time at paid work, and that was only partially explained by higher Internet use by teens and on days off from work. For reading and certain other behaviors, Internet use was sometimes associated with *increased* media use in these surveys. Moreover, no consistent decline in either social or media activities was found in either survey across this period of Internet diffusion, much in line with other national studies (Robinson and deHann, 2006; Robinson and Martin, 2009; Wellman et al., 2001). Nielsen/NetRatings (1999) found no reduction of TV viewing in Internet households.

Longer Historical Perspectives

The long-term ATUS and HETUS data collections have renewed interest in comparisons with much older time use data sets to establish possible longer term historical trends in various daily activities, particularly changes in the division of labor in unpaid work and childcare. Of particular importance are the very detailed United States Department of Agriculture (USDA) 'homemaker studies' and the UK Mass Observation records.

USDA 'Homemaker' Studies' 1923–35

The 1925 *Purnell Act* enabled US State Experiment Stations to use federal funds for research into the economic and social problems of agriculture by undertaking studies in rural sociology, and agricultural and home economics (Kunze, 1988; Pinkett, 1984). Studies of rural and town homemakers' use of time were carried out in a number of states including: Nebraska (Clark and Gray, 1930); Idaho (Crawford, 1927); Washington (Arnquist and Roberts, 1929); South Dakota (Wasson, 1930); Oregon (Wilson, 1929); Rhode Island (Whittemore and Neil, 1929); and Montana (Richardson, 1933). The primary data from all these studies have been missing for a number of years, although the findings are published in Agricultural Experiment Station and USDA Bulletins.

Over the periods 1924–28 and 1930–31, the USDA, with Hildegarde Kneeland as lead researcher, collected approximately 1500 week-long time use diaries from US 'homemakers' in rural and urban areas. The 1924–28 studies included both farm households (559, 69% of the total) and nonfarm homes (249, 31% of the total) in open country or in towns and villages of fewer than 2500 people, while the 1930–31 sample of 692 homemakers resided mainly in cities and large towns (USDA, 1944, p. 1). It is still unclear whether these were separate samples or part of the state-conducted studies listed above.

Recently 643 weekly time use 'summary records' (time budgets) containing totals of time allocated to 58 everyday activities across the 168 h of the diarists' weeks were rediscovered in the US National Archives; 566 (of possibly 808) of these are derived from the diaries kept by homemakers in the 1924–28 sample. Although the 'summary records' do not include biographical information about the diarists, they provide their names and postal addresses. Research at the Centre for Time Use Research (CTUR) has identified more than 95% of these diarists in one or more of the 1920, 1930, or 1940 US Federal censuses, allowing accurate estimation of ages and reconstruction of respondents' occupational and family circumstances.

Only 77 of up to 692 records survive from the 1930-31 'College Women' sample, but they are complete and include: verbatim 7-day diaries completed on each of the 77 respondents; 'supplementary information' questionnaires providing detailed information on household composition and characteristics, appliances and equipment, paid and unpaid help and some open-ended questions on enjoyment of homemaking and summary records for each homemaker's week and; 'summary records' for each diarist.

Harms and Gershuny (2014) contend that Kneeland's (1929) *Annals* article – which sets out what they suspect to be the first ever statement of the modern economists' case for extensions to National Accounts to recognize and include the monetary value of women's unpaid domestic work – is based in part on these studies and believe that these data derive from her own working materials.

Vanek (1974, 1978), Ramey (2009) and others have cited figures from tabular results published in various USDA Bulletins (e.g., Wilson, 1929) in their papers on the impact of household technology. However, Harms and Gershuny (2014) are the first researchers to use the original microdata since the USDA Bulletins were published. They used the resulting individual-level data set to extend the modeling of rural women's time use trends backward from the modern American Time Use Study and the 1975 Michigan Time Use Survey to the new 1920s evidence (the 1930–31 data await analysis). They find, after controlling for demographic and economic circumstances, consistent trends through the 85-year period: substantial decreases of time in routine household operations, and substantial growth in childcare and shopping time (**Figure 5**).

Figure 5 (a): US farm and small town married women from 1920s to 2000s: Decreasing work-time categories. (b): US farm and small town married women from 1920s to 2000s: Increasing work-time categories. Harms, Teresa, Gershuny, Jonathan, 2014. 85 Years of US Rural Women's Time Use. Sociology Working Papers 2014-15. University of Oxford.

Mass Observation

The UK Mass Observation project was an independent British social research organization that documented the attitudes, opinions, and everyday lives of the British people from 1937 to the early 1950s. Madge and Harrison (1937) and others recruited more than 500 volunteers (termed Mass Observers) to report on monthly observation tasks, including complete single-day diaries across an entire year (Gershuny, 1991). The Mass Observation Archive is a charitable trust in the care of the University of Sussex and contains papers generated by the original Mass Observation social research organization and newer material collected continuously since 1981 (www.massobs.org.uk). Only a small proportion of the original diary materials have been coded.

New Data Collection Methods

Diary Supplements: IT

The conventional four aspects of time (what, what else, where, and with whom) became a *de facto* standard as a result of the Szalai et al. 1965 study, and have remained the standard dimensions for time use reporting (e.g., Harvey, 2002) in the HETUS Guidelines (1998, 2008). Newer reporting aspects now included in more recent time use surveys include the emerging 'fifth' field registering whether or not the respondent was using a smart phone, tablet, or computer (e.g., UK National Time Use Study, 2014).

Wearable Cameras

In addition to amateur enthusiasts engaging in 'life-logging' activities, professional researchers are also using wearable cameras (e.g., MeCam, Narrative Clip) or applications on their smart phones and tablets (e.g., DayOne, Momento). Wearable cameras are hands-free (worn on a lanyard or pinned to clothing) and capture about three images per minute of everyday activities from the wearer's point of view; although they do not collect sound, they can log location using GPS. Special ethical considerations need to be taken into account, particularly issues associated with the informed consent of people whose images are captured by participants wearing the camera (Kelly et al., 2013).

Wearable cameras have been used mainly in small-scale, specialized health, and medical studies examining topics such as physical activity (Doherty et al., 2013), sedentary behavior (Kerr et al., 2013), dietary analysis/food diaries (O'Loughlin et al., 2013), travel behavior, (Kelly et al., 2013) and memory loss (Hodges et al., 2011). Researchers have also been experimenting with activity categorization and autocoding (Byrne et al., 2008; Wang and Smeaton, 2013).

It is only very recently that diary methods have been used in conjunction with wearable cameras. Currently underway is a UK study (150 participants) matching data from wearable cameras, time use diaries, and accelerometers to clarify and classify daily activities. One of the goals of the project is to validate and calibrate self-report diaries as a data collection instrument by coding 'streams' of continual day-long images from the wearable camera.

Holmes and Bloxham (2009) describe promising results from a US study using an 'electronic shadow' device that tracks a subject's daily activity by means of an observer who records each activity on that device every 10 s during the waking day.

Internet and Mobile Applications

Smart phones and tablets, with their wide range of 'applications,' offer researchers new approaches to capturing people's everyday time use. The smart phone applications provide time-tracks of location and personal energy expenditure, using GPS and motion sensors, as well as provide opportunities for respondents to register activities, purposes and other descriptive materials. Many people carry and use their smart phone (or tablet) with them throughout the day and use it regularly, enabling researchers to easily ask respondents follow-up subjective and objective questions.

Web-Based Data Collection

Researchers at the Vrije University in Belgium have designed a Modular Online Time Use Survey (MOTUS) as a pilot project to collect time use data using online registration methods (Minnen et al., 2013). A main goal of the study was to evaluate the comparability between online time use data and traditional paper-and-pencil diary data. The data collection took place in 2013, with 40 000 respondents (aged 18–75 years). The researchers believe that MOTUS will allow low cost, time-efficient, and high-quality time use data to be gathered (e.g., coding done at point of data collection, inconsistencies identified during collection via prompting, etc.). The online diary is based on the HETUS Guidelines (2008).

Smartphone Applications

Researchers from the Netherlands Institute for Social Research (Fernee et al., 2013) carried out a pilot time-diary study with 100 respondents using a smart phone application they designed. Before the pilot phase, they conducted several experiments to test how well participants with and without their own smart phones were able to use the appication. Results suggest that both groups were able to participate effectively, with some exceptions. A larger time use study with 2000 respondents is underway to allow comparison between smart phone and traditional paper diaries, both based on the 2008 HETUS Guidelines (2009).

Subjective Time

The QOL or positive benefits of engaging in particular daily activities is not always obvious, although social observers seem to concur that increases in daily activities like childcare, volunteering, and other potentially altruistic behaviors (as well as free time) represent improvements in a person's or society's QOL. In contrast, increases in time spent on routine housework, repair activities, and TV viewing are seen as less desirable. Nonetheless, it is important to have empirical support for such assumptions, and this is directly provided by the subjective time measures (Robinson, 2013a,b; Robinson and Gershuny 2013).

Subjective time measures fall into three categories, which are as follows: (1) *Affect* relates to enjoyment and satisfaction, with questions about how much enjoyment, pleasure, or happiness respondents experience from specific activities. (2) *Time pressure* concerns perceptions of time pressure and stress, with questions about feeling rushed, time crunch, and personal stress. (3) *Output* relates to questions about outputs from time inputs, such as being more satisfied with home meals or cleanliness. These have supplemented more 'objective' measures of output, like grades in school, house cleanliness, or obesity.

Fuller coverage of the subjective measures is provided in a separate topic section in this volume.

General Trends and Patterns in Time Use

Cross-National Results

Finally, multinational research reveals surprising activity convergences across most of the more than 30 countries studied (some identified below), although most of them are developed Western societies in Europe (that can afford to conduct expensive time-diary surveys). For example, Bittman (2000) found similar increases in free time since the 1960s in other countries, much as in the United States. In an analysis of all productive activity (contracted and committed time together) in 12 countries, Goldschmidt-Clairmont and Pagnossin-Aligisakis (1995) found the same basic equality of men and women in overall hours spent on such activities. A study of parental time with children found the same pattern of increased father childcare across six Western countries since 1990 (France being a notable exception), much as was reported in a 2004 study (Gauthier et al., 2004) for many other countries over this period. Robinson and Godbey (1999) found many similarities in both the trends and predictors of time use in Japan, Russia, and Canada. Gershuny (2003a) has extended these results to more than 15 other countries.

US Trends in Time Use

As noted above, diary data have been collected at roughly 10-year intervals since 1965 and have shown some consistent trends since then. The major overall trend has been in the form of a gender switch; paid work has been declining for men in contrast to paid work increasing for women, coupled with increased housework for men, and a large decrease in housework for women. Moreover, there is more general gender convergence evident in many other personal and free-time activities as well (Robinson and Godbey, 1999). Overall, there seems little evidence of a more hectic lifestyle, say in terms of less free time or sleep or declining sleep.

Other major general increases (for both men and women) are evident for childcare, TV viewing, fitness activities, and relaxing (and free time in general), in contrast to notable decreases in newspaper reading, hobbies, and work breaks. Many of these changes for those aged 18–64 years had been reported in Robinson and Godbey (1999). Data on activities for which estimate trend data are also available, mainly from

the GSS, the Survey of Public Participation in the Arts (SPPS), the PSID, and organizations interested in particular activities (like sleep or volunteering).

The General Social Survey

As illustrated in **Figure 4**, there are several GSS activities for which estimate data are available: work, TV and newspaper reading, religious attendance, sex, and several other types of social interaction. Analyses in Robinson and Martin (2008) and Marsden (2012) show the direction of 1972–2000 trends for many of these behaviors, particularly the declines in newspaper reading and church attendance (Presser and Stinson, 1998) and little consistent change in social activity. However, the GSS data show no change in TV viewing hours over the period 1972–2004, in contrast to the 70% increase in viewing found in the 2005 diaries compared to 1965. The PSID housework decline for women and increase for men is quite consistent with that shown in the diaries (Juster et al., 2003).

Summary and Conclusions

While the time diary is one of many options for measuring how people spend time, its general adoption across most Western countries thus far has produced a rich body of insightful results. This promises to increase in the future given the increased availability of continuous, large-sample, and high-quality government data, as in the many and varied applications of the ATUS (Robinson, 2009).

Diary data have raised serious issues about the accuracy of data obtained by more traditional 'time-estimate' questions, both in terms of simple amounts levels of time spent and in trends in these amounts across recent decades. Research undertaken with diaries supports the conclusion that the time estimates are open to the common survey problem of social desirability (Krosnick, 1998). While more definitive methodological research is needed as these ATUS data are more widely used, the diary method has showed promising results in terms of the major criteria of reliability and validity. It also needs to be noted that, although most of the data reviewed here are for those aged 18–64 years, the ATUS diary data are available for senior citizens aged 65+ years (Robinson and Godbey, 1999; Robinson, 2010). The ATUS now also provides activity data for large samples of US teenagers aged 15–17 years, and PSID diary data provide supplemental diary data for even younger children (Raley, 2006; Robinson and Godbey, 1999), often revealing the few hours American children apparently spend doing school homework, paid work, or household work.

Diary trends since the first national US diary study in 1965 indicate a number of unexpected societal changes, particularly in the converging lifestyles of men and women, who are now doing more equal amounts of not just paid work and housework, but most personal and free-time activities as well. Diary trends also indicate more TV viewing, childcare, and fitness activity, which has been offset by decreases in housework, eating meals, and newspaper reading. There also appears to be a notable increase in secondary activities, with evidence of increased multitasking (mainly involving TV, radio, and other newer media). This is reflected as well in the 20% point increase in the proportion of respondents who say they are often doing two or more activities at once (Bianchi et al., 2006).

Based on these subjective data, it could be taken as an encouraging sign that the trends in US diary hours do follow a generally hedonistic direction, in that Robinson and Godbey (1999) find people report spending increased time on activities they find more enjoyable (like childcare and free-time activities) and less time on the things they do not like to do (especially housework). Along the same line, Bianchi et al. (2006) report increased time spent on childcare, especially interactive or 'fun' activities with one's child. Moreover, these same long-term *time* trends are found in other countries as well (Bittman, 1998; Gershuny, 2003a). Conversely, time spent on the most enjoyable daily activity of sex has not been increasing since 1989, in spite of the increase in Viagra, Internet services and pornography, and other marital aids (Robinson, 2010).

In terms of public policy, time diaries provide clear evidence of several social inequalities. In the case of the division of housework between men and women, **Table 4** shows that both men and women rate housework as quite low in terms of enjoyment. Yet women continue to do twice as much of it.

The 'Take Back Your Time' movement (De Graaf, 2003) proposed that American workers stop all paid work after mid-October, so that their total annual work hours would be equivalent to those of European workers. Yet, Hochschild (1997) found in one company that it was other workers themselves who sabotaged innovative family friendly policies to reduce work hours. The National Sleep Foundation has raised alarms about sleep deprivation as a national crisis, although time diaries show no decline in sleep over the last 40 years (which holds steady at about the recommended 8 h a night). The 'turn off your TV' movement has designated 1 week a year for people to leave their sets off and to participate in more potentially gratifying activities instead. However, **Table 2** suggests that, although people rate TV in general as relatively low on the fun meter, the programs they watched on the diary day rated far higher in enjoyment.

Of all the public potential policy issues related to time use, possibly the most impressive is the lack of solid data on the marginal outputs that workers produce and obtain for their inputs of work time. Some data suggest that the same work productivity can be achieved with 20–50% less

Table 4 SWB item intercorrelations and factor loadings

	Sad	*Pain*	*Tired*	*Stress*	*Happy*[a]	*Factor loading*
Sad		0.37	0.27	0.49	0.32	*0.75*
Pain			0.34	0.34	0.17	*0.67*
Tired				0.37	0.17	*0.62*
Stress					0.32	*0.77*
Happy						*0.54*

time spent on the job (Parkinson, 1957; Schor, 1991; Schuman et al., 1985) and that many workers put in simple 'face time' to impress their employers.

The findings reported in **Tables 4 and 5** represent an important first step toward gaining more nuanced insights into time use statistics, but more holistic study designs – such as a 'representative ethnography' that combines the insights of observation with the generalizability of representative sampling of respondents could provide more enlightened meanings (Robinson and Meadow, 1982). Although confined to northern Californian middle-class parents, the observational study of Darrah and Murphy (2009) provides an impressive model. Diary data allow researchers to document what people are doing, but we need to find out more about why, with whom, for whom, and to what ends people are using their time.

Time Use Research: Subjective Time Use

John P Robinson, University of Maryland, College Park, MD, USA
Jonathan Gershuny, University of Oxford, Oxford, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The quality of life (QOL) or positive subjective benefits of the time people spent engaging in particular daily activities is often not obvious, although social observers seem to concur that increases in daily activities like child care, volunteering, and other potentially altruistic behaviors (as well as overall free time) represent improvements in a person's or society's QOL. In contrast, increases in time spent on routine housework, repair activities, and TV viewing are seen as less desirable. Nonetheless, it is helpful to have empirical support for many of these assumptions, and this is directly provided by the subjective time measures reviewed here.

Introduction

Subjective time refers to attitudes and feelings related to various activities or uses of time. Subjective time measures in this article fall into three categories:

1. *Affect* relates to enjoyment and satisfaction, with questions about how much enjoyment, pleasure, or happiness respondents obtain from specific activities (or from their lives more generally), as shown in Tables 1 through 4. These mainly include how people feel momentarily, or in 'real time' as in a time diary, but can be extended to include more general quality of life (QOL) feelings, and there is now evidence in the American Time-Use Survey (ATUS) that the two are connected and may predict each other.
2. *Time pressure* concerns perceptions of felt time pressure and stress, with questions about feeling rushed, time crunch, and personal stress.
3. *Outcome* concerns questions related to outputs from time inputs, such as being more satisfied with one's job, house cleanliness, or how well one's children are doing in life. These can be supplemented with more 'objective' measures of output, like grades in school or health

Affect

Specific attempts to identify how time-diary keepers feel about their daily activities began in the first U.S. diary study in 1965, when respondents were asked about how much satisfaction they generally derived from different daily activities, and about what were their most and least liked activities during the diary day (work was listed relatively often in response to both questions).

In contrast, respondents in waves 2 and 4 of the subsequent 1975 diary interviews *were* asked to give specific enjoyment ratings to the 19 common daily activities shown in Table 1, using a 0–10 scale, where 0 meant 'Dislike a great deal' and 10 meant 'Enjoy a great deal.' Average scores on these 1975 general activity scales from Juster and Stafford (1985) are ordered by level of enjoyment on the right side of Table 1 (alongside the parallel diary-based ratings collected in 1985 on the left side, as described next).

In their 1985 telephone interviews, then, diary respondents were asked to rate each activity in their time diary on that same 0–10 scale employed in the 1975 general ratings, as averaged on the left side of Table 1. In other words, in addition to the usual diary follow-up questions on secondary activities, location, and with whom, 1985 diary respondents were also asked to rate how much they enjoyed each such activity 'in real time' rather than generally. Some differences by the two Table 1 rating contexts are discussed below, although it can be seen that most differences are not notable.

Indeed, Robinson and Godbey (1999) found that the rank order of activity affect for these ratings in the diary correlated about 0.70 with Juster and Stafford's (1985) ratings of activities in general. But there were important exceptions. First, 1985 workers rated their daily *paid work* activities as less enjoyable than 1975 workers rated their work in general. Second, 1985 diary respondents rated their *TV viewing* episodes as more enjoyable in their diaries than 1975 respondents did in general (perhaps explaining why people may inadvertently watch more TV than they would like). It was also found that these 1985 diary enjoyment ratings were highly predictive of their TV viewing times in diaries collected 3 months later, a case of attitudes predicting behavior, and one that held for other diary behaviors as well.

Social Well-Being Ratings in ATUS 2010

One important distinction between the 1985 enjoyment ratings in Table 1 and the 2010 Social Well-Being (SWB) diary ratings described next is that the 1985 enjoyment ratings used only a single 0–10 rating scale for all activities, as opposed to the five descriptive ratings in Table 2, each of which was rated using 0–6 unipolar scales. This greater breadth and coverage meant, however, that they could only be asked for three of the activities in each respondent's diary, thus missing the opportunity to examine the full ebb and flow of daily emotions (to test Gershuny's (2012) intriguing 'diminishing utility of an activity across-the-day hypothesis,' for example).

From Robinson, J., Godbey, G., 1999. Time for Life, rev. ed. Penn State Press, State College, PA.

These 2010 SWB ratings were based on the promising pilot-study results of a Princeton University-led team of prominent social scientists (e.g., Krueger et al. 2009; Kahnemann et al. 2004). Encouraged by these results, the 2010 ATUS began enhancing respondent time-diary accounts by asking their diary-keepers how they felt, using these five Princeton-based (SWB) feelings (sad, pain, tired, stress, and happiness), in reference to while they were engaged in these specific diary activities. Thus, ATUS respondents were thus asked how they felt while doing *three* such activities (chosen at random), using scales running from 0 (no such feelings) to 6 (maximum such feeling). The distribution of their responses to these five scales is shown in Table 2, along with their overall average scores on each of the five 0–6 scales (a sixth adjective item ('meaningful') was disregarded because it did not correlate with the other five).

While Table 2 shows how differently these ATUS respondents generally felt on each of the five major SWB adjective scales, it also shows that these five disparate feelings/adjectives are still significantly related to each other, despite their covering a varying range of emotions, both positive and negative. Indeed, in the last column of Table 3, it can be seen that the five can be reduced to form a single dimension of SWB based on a factor analysis. This provides a justification for summing the five items into a single overall SWB index, potentially running from 0 (most positive on all five) to 30 (most negative on all five). These average scores were then subtracted from 13.0 to generate a higher positive score for each activity, with higher scores now reflecting a higher SWB to ease interpretation, with this average score of 3.0 in Table 4 still indicating how strongly positively these diary activities were rated. These scores are then ranked by SWB activity score in Table 4, as described in more detail below.

Table 2 Percent of 2010 ATUS respondents giving each SWB scale score

Score	*Sad (%)*	*Pain (%)*	*Tired (%)*	*Stress (%)*	*Happy (%)**

Average	0.65	0.92	2.30	1.42	5.29	
*Reverse score					1.71*	Sum = 7.0

At the same time, Table 3 indicates that these SWB intercorrelations are not that strong, being below 0.20 for two of them with (reverse-scored) happiness. Even the negative correlation between the virtual antonyms sad and happy is only −0.32, indicating the aversion most respondents felt about rating daily activities negatively (as evident in Table 2). Thus, more than 70% of respondents gave absolute zero (0) ratings to the adjectives 'sad' and 'tired' in rating their daily activities. Nonetheless, the five items do intercorrelate as well as many other accepted scales in the attitude literature (such as trust in people or anomia/alienation in the General Social Survey (GSS)). That should not discourage researchers from examining 'contradictory' activities, such as those that bring people happiness but are also stressful or tiring (e.g., Wang, 2013)).

The overall ratings shown in Table 4 thus outline and rank almost 100 diary activities according to the type of activity and from top to bottom in how they scored on the five-item SWB

Table 3 SWB Item Intercorrelations in ATUS 2010–12

measure. This is shown horizontally across columns (from work to personal care to free time to travel activities) and vertically in ordered rows, with highest SWB ratings at the top (about 6.0) to lowest ratings at the bottom (0). More detailed interpretation of the origin and meaning of these ratings is reported in Robinson (2014).

This newly derived five-item SBW scale from ATUS ratings in Table 4 does largely replicate the general feelings about various daily activities identified in a 1985 U.S. national time study (Robinson and Godbey, 1996; Robinson, 1993) and in a 1996 U.K. national survey (Gershuny, 2012), also using a single enjoyment scale as its QOL measure. Thus, social

and visiting activity, interactive activities with children, and religious/volunteer activities top the list of favorite daily activities as rated in 'real time' as well as in general. Routine household tasks and attending to medical and other personal needs rate at the bottom. (That also tends to be the ranking reported from the U.S. and French urban community studies reported in **Table 3** of Krueger et al. 2009).

What is most surprising, important (and troubling) in these new ATUS ratings, however, is the notably lower SWB ratings given to paid work activities. This perhaps reflects a disturbing trend in life at work, jobs which many workers may endure simply to keep their basic personal and household needs afloat. These again are momentary diary ratings, but finding that these ratings are far below those in 1985 remains a concern. These low ratings are also at odds with responses U.S. workers give to general survey questions about the role and importance of work in their lives (Robinson and Godbey, 1999).

Of further concern is the below-average ratings given to Americans' most prevalent free-time activity of TV viewing. TV may serve to offset the even-lower rated activity of paid work, but it still rates notably lower than almost all other choices of a free-time activity. Earlier results from Kubey and Csikszentmihalyi (1990) suggested TV was not that much lower in enjoyment ratings than other activities, but that it was more deficient on adjectives 'challenging' and 'alertness' (not included in the present SWB ratings). Thus, these findings again suggest that engaging in more active free-time activities could be one road to improving America's collective QOL.

Many of the same conclusions about favorite activities are reached from the single question used in the Statistics Canada diary studies, as analyzed by Michelson (2011). He also found Canadian respondents unable to identify a single favorite activity on the diary day to rate themselves as lower in overall life satisfaction, a diary-overall difference discussed as our next topic.

Overall Life Satisfaction and Happiness

The above diary-based measures of momentary activity affect are rooted in a much larger and earlier survey tradition that has been asking about the public's personal QOL issues more generally, as highlighted and strengthened during the 'social indicators movement' of the 1960s, and reinvigorated by more recent attention from leading economists. Perhaps the most widely cited measure in these efforts has been the 'happiness question' first asked in the 1930s but now a feature of QOL time-series monitors like the GSS (e.g., Smith, 2011; Marsden, 2012). Here, the economists, like many other social observers, are quick to contrast the lack of increased happiness (or other positive affect) in the GSS or other trend surveys across periods of marked increases since the 1950s in economic prosperity and standards of living.

That self-rated happiness question had been intensively investigated by Bradburn and Caplovitz (1966) prior to its being asked continuously by the GSS since 1972. It simply asks respondents whether they feel 'Very, Somewhat, or Not' happy. The question has consistently been shown to correlate positively with several demographic factors, such as higher income, being married, being more educated, older and White – as well as with other subjective QOL variables, such as alienation, self-esteem, locus of control, optimism and life satisfaction, among others (Andrews and Robinson, 1991).

In one general overview study using long-term time-estimate (not diary) data from the GSS since 1972, Robinson and Martin (2008) found that happier people reported more frequent social visits, attendance at religious services, and reading of newspapers, again after demographic predictors of these activities were taken into account. In contrast, happier GSS people reported watching much less TV. These findings are generally reinforced by diary-based ratings in **Table 4**. Further clues to time or life factors more important to higher long-term QOL can be found in the pioneering surveys of Campbell, Converse ad Rodgers (1978) and Andrews and Withey (1976).

Thus, a welcome recent addition to the ATUS is the inclusion of a long-term QOL question to relate to the momentary diary-based affect measures in **Tables 1–4** This is a 'ladder' question developed by Cantril (1965), on which ATUS respondents are first asked to think of their best possible life as being a 10 (at the top of the ladder) in contrast to a 0 as the bottom rung of the ladder for their worst possible life. ATUS 2012 respondents gave an average score of 7.0 on this measure, and when their ladder score was correlated with each of the five feeling items in **Table 3**, the highest value was with the happy item ($r = 0.31$), indicating this to be the central feeling implicit in their ladder rating (although the other four adjectives are significant as well, not much predictive power is added by including the five-item SWB score in **Table 4**, which correlates 0.37 with the ladder; moreover, the disregarded 'meaningful' item correlated only 0.03 with the ladder, providing further justification for disregarding it). The important point here however is that there is a clear connection between diary and overall QOL ratings, one that does not evaporate when they are adjusted for other QOL predictors.

These studies provide evidence of a, perhaps not surprising but reassuring, connection between the general and the momentary ratings, in that generally happy people also report being happier during their diary activities, and vice versa. That may be a finding that could be simply expected or explained as a result of a survey 'response set,' but it probably has wider social and scientific implications. It is not clear which has precedent, but it suggests that engaging more in the higher rated activities in **Table 4** on a daily basis may be associated with a more satisfying life in the longer run.

Time Pressure

A general consensus seems to have emerged that the pace of U.S. daily life is speeding up (e.g., Rosa, 2005; Rosa and Scheuerman, 2010), authors who joined and expanded on conclusions from several other researchers in echoing or amplifying on the faster-paced lifestyle theme, including *Work without End* (Hunnicutt, 1998), *The Overworked American* (Schor, 1991), *Busy Bodies* (Burns, 1993), *Faster* (Gleik, 1999), *Fighting for Time* (Epstein and Kalleberg, 2004), *Work to Live* (Robinson (2003), *Take Back Your Time* (de Graff, 2003), and *Busier Than Ever* (Darrah et al., 2007). Several other prominent social scientists contributed essays further echoing or amplifying on this theme in a special issue of the journal *Social Research* on busyness edited by Mack (2005).

Despite this broad consensus about an increasing time scarcity, little empirical documentation is in evidence of its presence, let alone its increase. The American Psychological Association (APA 2012) has begun to monitor stress levels in the U.S. public on an annual basis since 2007, although with self-selected samples not generalizable to the U.S. public as a whole. The APA's 2012 report noted that extreme stress levels in their samples have steadily *declined* from 32% in 2007 to 22% in 2011. (At the same time, more than 40% of these same respondents also estimated that their stress levels had *increased* in the previous 5 years, even though that is not reflected in their personal stress ratings per se).

Earlier, Robinson and Godbey (1999) had reviewed three short measures of subjective time pressure: (1) stress questions developed and measured by the U.S. National Institutes of Health in the 1990s; (2) a 'time crunch' scale of 10 Yes–No questions; and (3) two earlier questions asking respondents how often they felt 'rushed' or had excess time on their hands. The latter had the advantage of having been asked across several decades starting in 1965, asking the two main questions in **Tables 5** and **6** to capture these feelings. One asked how rushed respondents generally felt, and the others how much excess time they felt they had (Robinson and Godbey, 1999). These have been replicated in several subsequent national surveys, with **Table 5** showing almost a 10-point increase in feeling rushed during the 1990s, but a return to almost the same 1965 levels of feeling rushed in 2010. This decrease was found despite the recent proliferation of new time-intensive IT technologies (Robinson, 2013). While Americans aged 18–64 years had increased their feelings of being 'always' rushed, from about 25% in 1965 to about 35% in the 1980s and 1990s, this trend came to a decided halt in two surveys in 2009–10 (Robinson, 2013).

This article centers on the final two columns in **Table 5**, updated readings from: (1) the 2010 GSS survey and (2) a national 2009 omnibus survey conducted at the University of North Florida (UNF). These updated **Table 5** data are summarized graphically in **Figure 1**.

This **Table 5** trend is thus quite counter to the societal consensus that the pace of daily life is speeding up, as proposed by Rosa and other authors. Contrary to such expectations, both of these most recent surveys now show decreases in percents feeling always rushed among those in the 18–64 age-group, a 6-point drop to 28% in the 2009 UNF survey and a larger 9-point drop to 25% in the 2010 GSS survey. **Figure 1** and **Table 5** also show that responses to the second subjective time question on having excess time (in terms of 'never' having time on one's hand and not knowing what to do with it) had remained fairly constant. These declines thus put the 'always rushed' levels in 2009–10 at about where they were in the 1970s. The declines were not simply due to unemployment, as they were found among employed respondents as well.

Overall, then, the two sets of results are rather surprising, given the plateau of readings at about 35% 'always rushed' levels since the 1980s, and in light of all the new time-intensive IT technologies and the 2007 economic crises. In

addition to these decreases in societal subjective time pressure, some of their other QOL implications are surprising as well.

QOL Implications of Subjective Time

These two subjective time attitudes have also been found to have implications for more direct measures of a person's QOL, with the percent of 'very happy' responses used as the major indicator of one's QOL. The 1972–2012 trends in this very happy category have proved remarkably steady over this 40-year period, averaging about 33% across the decades. Table 6 shows that these 'very happy' responses have also been consistently and significantly related to both subjective time questions, both in previous GSS surveys (1982, 1996, and 2004), as well as in the 1976 pioneering study of Campbell, Converse and Rodgers (1978). Thus, in the 1982 GSS, only 29% of those always feeling rushed said they were very happy, compared to 35% of those sometimes feeling rushed and 39% who felt 'almost never rushed,' a regular increase of 10 percentage points. Similarly in 1996, the difference was from 27% to 33% and to 37%, again a regular progression of 10 points. As shown in Table 6, in Campbell, Converse ad Rodgers (1978) the progression was a slightly greater 13 points (from 28% to 33% to 41%). Much the same pattern is found in both 2009–10 surveys in Table 6. Both data sets were poststratified to match Census Bureau demographic figures on gender, age, race, marital status, education, and income. (Figure 2)

Figure 1 Trends in 'always rushed' responses: 1965–2010.

Figure 2 Happiness levels for combined time attitudes 1976–2010.

Further support for Table 5 comes from a question concerning whether Americans feel more pressure from this factor of time or from its competing resource of money. This question has shown a marked recent swing since 1998, when the majority (52%) of Americans said that lack of time was of more concern to them than lack of money. That dropped to 33% in 2013, a decline that was reported across all age, education, and income groups, not just the unemployed. As expected, and as in earlier surveys, it was the case that those feeling lack of time more than lack of money did have notably higher incomes, but even higher income groups reported the recent increase in choosing lack of money over lack of time.

Stress

Given the great medical concern and societal attention paid to the stressful lifestyles in America, it is surprising that there are so little data using standardized trend questions on stress from representative national samples. The National Center for Health Statistics did include a direct question on perceived stress in its very large 1985 to 1998 surveys, and it did find a significant rise from 50% to 56% between 1986 and 1993, but then a surprising decline to 48% in 1995. Unfortunately, this question, that had the same pattern of correlates as those in Table 5, appears not to have been asked since then to track more recent levels and correlates of stress.

Time Crunch Scale

Robinson and Godbey (1999) reported results from a 1993 nonprobability national survey that developed a 10-item measure of feelings of time pressure, with an average of about 33% of respondents agreeing with these items (about the same proportion as who describe themselves as always rushed). As with the rushed and stress questions, women and those aged 25–44 years were most likely to respond being under more time crunch. The scale has not been replicated in the United States, but it has been repeated in Canadian national diary studies, as well as in other countries (Michelson, 2011).

Other Questions

Another single item asked respondents in that 1993 survey whether they would be willing to give up a day's pay to get a day off from work, to which nearly 50% said 'Yes,' and that

proportion has remained at about that level in subsequent U.S. surveys. On the other hand, using a more balanced question, only 13% of respondents said they would like to work fewer hours (compared to 35% who wanted more work – and 52% who said the same work hours). That latter result is in keeping with the small minority of 18% of workers in both 1975 and in 1998 who reported being 'very tired' at the end of a workday, here suggesting few workers face little overall time problem with their workload.

Time pressure concerns are also evident in questions asking respondents whether they have more or less free time than 5 years previously, and here far more respondents say 'less' free time than 'more.' In family surveys, when asked whether they spend enough time with their children, most parents say 'not enough,' even though mothers (but especially fathers) are spending more time with their children than 10 or 20 years ago (Bianchi et al., 2006). Parallel questions about time with one's spouse or by oneself drew similar or higher levels of 'not enough time' responses. Other GSS questions have asked perceptions of how well balanced one's work and family lives were. Robinson and Godbey (1999) found that less than 30% of wives said they wished their husbands would help them more with the housework or with child care, and that has not changed much since then.

We turn next to a different type of data, one that attempts to provide greater insight into the results of these time measures, and their QOL implications.

Outcomes from Time Inputs

Here, the concerns are about the productivity or consequences of various ways of spending time. For example, does one feel that the hours devoted to an activity have any parallel in increased output? Thus, one set of survey questions has asked parents about how well their children are doing in life, about their satisfaction with the amount of time the family spends together, or about awareness of where their children are at times when they are not with them (Bianchi et al., 2006). Other survey items have asked how satisfied respondents are with the cleanliness of their homes (Robinson and Milkie, 1998) or the quality of the family meals (Juster and Stafford, 1985).

A few studies have examined time's relations with more objective measures of output. Schuman et al. (1985) found little relationship between study time and grades in school. Robinson and Godbey (1999) similarly found little relation between time spent on housework and respondent satisfaction with household cleanliness, or on ratings of that cleanliness either by the respondent, or by the interviewer who observed the dwelling. Nor did they find that presence of household appliances helped reduce housework time, perhaps because it is the busier and more ambitious families that buy the technology in the first place, as found earlier in Morgan et al. (1966).

Some more promising economic advances in linking time inputs and outputs or societal welfare have been recently proposed by Bittman and Ironmonger (2011), who presented a typology outlining several options to valuing time by using a person's simple wage rate. Folbre (2009) elaborated ways in which time-use data can improve both subjective and objective measures of living standards, pointing out fundamental flaws in the ways conventional economics puts values on different activities. Hamermesh (2009, 2013) has proposed other new ways economists need to use more economic theory to guide their analyses of time.

Alternatively, Goodin et al. (2008) asserted how time is an inherently superior metric of welfare than money, reversing the usual process of valuing time in dollars and instead expressing money in terms of the time required to earn it. Their arguments are built around the central idea that the *ability to choose* how to allocate one's time lies at the core of a positive notion of freedom. The authors developed a new standard of welfare from the idea of escape from the 'realm of necessity' by defining 'discretionary time' as what is left after necessary minimum time that must be devoted to personal care, paid work, and nonmarket work. Discretionary time thus represents an advance over the more conventional category of 'free time' as a new metric of welfare.

On the negative end of the welfare scale, there is the concern about the possible negative impacts of time spent eating. Zick and Stevens (2011) report that, while time spent eating as a primary activity has remained relatively unchanged over previous decades, eating time as a secondary activity has risen significantly – particularly as an accompaniment to TV viewing. In Australia, Brown et al. (2011) presented evidence that adolescent TV viewing is accompanied by increased consumption of high-calorie snack foods. The ATUS has begun to ask new questions relating time use with food consumption and fitness activity to examine further linkages between daily activity and obesity (Janes et al. 2011).

Abstract

Sociocultural constructions of time and time-reckoning are central topics of anthrological inquiry. Many cultures lack an explicit category 'time.' Still, time is everywhere present, in numerous local figurations that may or may not evidence a few universal forms. This article offers a representative review of time cross-culturally that focuses on some of the important concepts, debates, and intriguing new areas of investigation. The article, by discussing possible universal configurations of time – e.g., human lifecycle and bodily processes, seasonality, celestial patterns, binary constructions, and the opposition between incremental/linear/irreversible and episodic/cyclical/repetitive forms of time. Next, some traditional anthropological ideas about time are discussed: time categories and conventions are 'social representations' that mirror the organization of society (e.g., kinship groups), the political manipulation of time, the existence of multiple or layered forms of time which are not necessarily integrated into a single unifying system, ritual versus mundane time, and the linguistic relativity of time. Finally, some recent topics of concern are addressed, specifically, the spatialization of time, embodied time, gendered time, and the 'end' of time.

Sociocultural constructions of time and time reckoning are now central topics of anthropological inquiry. Many cultures lack an explicit category 'time.' Still, time is everywhere present, in numerous local figurations that may or may not evidence a few universal forms, and thus the anthropological spectrum of research, theories, and contentions is vast (Gell, 1992; Munn, 1992). I offer here a representative, nonprogrammatic review of the topic that focuses on some of the important concepts, debates, and intriguing new areas of investigation.

Universal Time

Certain natural phenomena appear to be universally temporalized in terms of periodicity and, in some but not all cultures, progressive quantification: the human lifecycle and bodily processes (e.g., menstruation), seasonality, celestial patterns, day/night, and so forth. The same is true for the reproduction of social order by generation and various social and kinship groups. All societies regularly coordinate labor, occasionally punctuate the tempo of everyday life with ritual, and envision some type of past, present, and future. Calendrical arrangements of days, weeks, months, and years are also universal – but, again, not everywhere counted. In anthropological theory, time is implicitly understood to be binary. For example, all cultures accommodate conceptual categories and linguistic terms for duration and sequence, which are often said to be the basic forms of time. Leach (1961) proposed that time is a social construction rooted in two basic human experiences: the repetitions of nature, and the irreversibility of life. Many anthropologists contend that all societies possess both incremental/linear/irreversible and episodic/cyclical/repetitive forms of time – which are not necessarily antithetical since time cycles can return to the 'same logical, not temporal, point' (Howe, 1981). While Farriss (1987) claims that any one mode can incorporate the other, Leach proposes that all religions deny the finality of human mortality by subsuming linear time under a cyclical framework. Birth and death become two phases of an eternal sequence. Leach also claimed that time is everywhere a 'sequence of oscillations between polar opposites.' This temporal pendulum is related to basic sociological processes such as reciprocal gift-exchange and marriage. More recently, Gell (1992) argued that all culture-specific patterns of temporality are variations of two cognitive modes: an A-series which orders events according to relative notions of pastness, presentness, and futurity, and a B-series of absolute before/after.

Social Time

Universal conjectures notwithstanding, most anthropologists focus on local notions of time and subscribe to the Durkheimian thesis that time categories and conventions are 'social representations' that mirror the organization of society. This sociological perspective is best exemplified by Evans-Pritchard's (1939) elegant study of the East African Nuer, which is perhaps the most widely-known anthropological account of a distinctly non-Western style of time. Nuer 'oecological time,' which is cyclical or seasonal, reflects the environmental rhythms of cattle pastoralism. More importantly, Nuer indicate time but they lack an abstract chronological system that is numerical, cumulative, uniformly incremental, and measurable. Beyond the year, Nuer speak about temporal duration, intervals, and sequences with sole reference to 'structural time' or significant genealogical events in the social system – say, the division of a lineage, or the birth of an age set. Since Nuer genealogies are fixed at a depth of five generations, too, the passage of time is contained within a static framework. Similarly, there is considerable debate over whether or not the terminological groupings and repetitions in many kinship systems freeze, reverse, or emphasize the passage of time (Silverman, 1997). Here, too, the opposition between cyclical and linear time is a leitmotif of anthropological analysis.

Cultural Time

The Durkheimian approach to time, enshrined in British social anthropology, anchors temporal conceptions to social organization. An alternative approach to time, represented by the 'interpretivist' tradition of American cultural anthropology, highlights the symbolic dimensions of time. Here, analysis seeks to discern the relationship between general temporal attitudes and the overall emotional emphases and focal symbols of a cultural worldview. Geertz (1973) suggested that the cyclical structure of Balinese kinship, naming, and calendrical systems 'don't tell you what time it is; they tell you what kind of time it is.' In a celebrated passage, Geertz concluded that 'Balinese social life takes place in a motionless present, a vectorless now' in which 'time lacks motion because Balinese social life lacks climax.' Moreover, the Balinese 'immobilization of time' is linked to the 'anonymization of persons.' Ultimately, the formal complexity of Balinese calendars pertains not to social order but to the unique, somewhat aesthetic themes and tones of Balinese culture and personhood. Whereas Evans-Pritchard pioneered the study of how others think about temporality, Geertz has been an inspiration to anthropologists who seek to understand how others experience time.

Political Time

One key debate in the anthropology of time, then, concerns the locus of analysis – broadly speaking, society vs. culture – and the question of whether or not time configurations can be reduced to a more elemental, causal factor such as human ecology. Another quarrel arises from the materialist division between infrastructure and superstructure. Bloch (1977) criticized Geertz for failing to distinguish between ritual time, which does differ significantly crossculturally, and universally cognized 'normal' time that organizes practical activities. Hierarchical societies, Bloch continued, tend to elaborate a ceremonial view of timeless time. Consequently, ritual concepts of time are ideologies that sustain everyday productive inequalities. But while Geertz, in this view, may be guilty of foregrounding difference or 'radical temporal alterity,' and thus neglects the politics of time, Bloch himself assumes that people everywhere subscribe to the same 'practical reason,' which remarkably resembles the economic concerns of Western Marxism. Many anthropologists emphasize the lability of time concepts and, more recently, the political manipulation of time. The Northern Thai calendar, which is oriented around a 'fatal quality of time,' enables post hoc explanations of misfortune that exonerate individuals from personal blame (Davis, 1976). The Kodi of Indonesia, for whom calendrical knowledge is prestigious, manipulate temporal sequences and durations, question the timing of ceremonial feasts and other public events, and strategically stage disruptions (Hoskins, 1993). The Kodi calendar is also a 'debating ground' as traditional forms of time now clash with exoteric calendars associated with the state, Christianity, and modernity. Multiple, or layered, forms of time which are not, moreover, necessarily integrated into a single unifying system are common. One temporal series may regulate markets, while another system organizes lunation. Time is often contextual – as well as competing and seemingly contradictory. Kabyle precapitalist peasants of Algeria submit to the present but exalt foresight within the temporal horizon of the 'forthcoming.' They also view the future – which capitalist hubris, in this view, seeks to predict – as a void known only to God (Bourdieu, 1963). A final note on the politics of time: when competing groups anchor their prestige in a politico-ritual system to ancestral primacy, the mere assertion that a temporal series, or time itself, has a specific beginning point or location is inevitably political since it denies the validity of rival times. This is true for small-scale societies as well as the contemporary United States, which remains embroiled in debate between evolution and creationism.

Ritual Time

Not only is the differentiation of ritual from mundane time important to many anthropologists, but so is the construction of time within ritual itself. Humans tend, wrote Leach (1961), to conceptualize time as a repeating series of different intervals. Each year is distinctive but they all begin and end with an identical festival. Significant calendric events are everywhere marked by ceremonial antics and attire that are censored from everyday life. These periodic ritual inversions or 'rites of passage' actually create time by introducing intervals in social life. Yet Barnes (1974: pp. 128–129) offered the opposite view for the Kédang of Indonesia: ritual insures precisely that time is not cyclical – that the dead, for example, are irreversibly dead, and that calendric cyclicity is unable to prevail over linear temporality. From a different perspective, Gell (1992: pp. 37–53) recently evoked Lévi-Strauss and argued that the ritual reversal or regression of normal time among the Umeda of Papua New Guinea resolves problems that arise from the imposition of 'cultural' conventions such as temporal classifications onto the 'real' or 'natural' world.

Language of Time

Unlike spatial deixis, the linguistic study of time remains sparse in anthropology. Yet the famous Sapir–Whorf hypothesis of linguistic relativity was initially popularized through the alleged absence of Hopi verb tenses (now disproved). Still, language shapes our experience of the world, including time. Hence, the Trobriand Islanders of Papua New Guinea are unable to discuss and conceptualize linear, chronological sequences of events (Lee, 1950). They have no time line but only temporal points organized as noncausal patterns with 'at most a swelling in value.' Devoid of linguistic temporal connections, Trobriand events are self-contained: 'a series of beings but not becoming.' Related studies of language and time include past vs. future-oriented locutions (e.g., Dundes, 1969), orality vs. literacy (Goody, 1991), and cognitive 'maps' of spatiotemporal passage (Frake, 1985).

Spatial and Bodily Time

The spatialization oftime and the temporality of space are topics of growing anthropological interest (see Munn, 1992).

Many cultures – e.g., Melanesia and Aboriginal Australia (Silverman, 1997) – understand the primordial creation of the universe through a series of ancestral migrations, radiating outwards from an origin place, that simultaneously generated space and time. But other cultures possessing a temporal topology, such as the Iraqw of Tanzania, lack an origin: 'there is no zero point against which to set a regularized chronology' (Thornton, 1980: p. 184). Spatiotemporal mythologies occur across lowland South America, where time and space are also embodied. The passage of time in the external world – the flow of a river, the movement of the sun – represents the human life-cycle. Conversely, the temporal unfolding of physiological processes such as sexuality and alimentation are projected onto the local topography (e.g., Hugh-Jones, 1979: Chap. 7). The experience of time is thus understood through a bodily schema, specifically, the circulation of substances into and out of the body, and wider cycles of birth and death.

Gendered Time

The relationship between gender and time is another promising area of anthropological study. The riverine Eastern Iatmul of Papua New Guinea associate water with uterine fertility, death, and the inexorable erosion of land and trees that threatens to regress the cosmos back to the timeless and feminine era that preceded male creation (Silverman, 1997). Like the river, female time flows to uncertainty. Male time, often conceptualized as the planting of trees and the establishment of villages, progresses forward against the flow of female temporality. But the arboreal ascendance of masculine structure is illusory. The river and rainy season floods ultimately prevail. All men can do to stem the feminine tide of regressive time is plant trees, build houses, and enact rituals. Weiner (1991) also discusses the gender of time in a Melanesian society, and links temporality to linguistic iconicity and motions through the landscape and body.

The Future and End of Time

Anthropologists are no longer content merely to bemoan the end of the 'time of the primitive.' Nor do we continue to define non-Western 'Otherness' as an essentially temporal construct, communities who are removed from us in both space and time (Fabian, 1983). Instead, anthropologists are increasingly interested in historical conjunctions and contemporary practices that blur the distinctions between local and global times. Through temporal ambiguities, local people exercise creativity and resistance. While all societies allocate time between different activities (Gross, 1984), the spread of global capitalism and wage-labor has imposed on people everywhere computational, monetary, and aggressive notions of temporality such as saving, wasting, and fighting against time. But the future of time, to invoke a common idiom, is not confined to 'time is money.' The millennial turn encouraged many communities to confront the historical dissonances of culture contact by rethinking conventional notions of past, present, and future, cyclical and linear time, tradition and modernity, and the relationship between the biblical apocalypse and ancestral spirits. The millennium was a time to ponder the end of time (Scaglion, 2000) – as well as, in the context of Y2K, the opposition between 'virtual time' and 'real time.' Thus the opening decades of this millennium, including its end-of-time scenarios, will doubtless prove to be a propitious era for the anthropological study of time both globally, locally, and in the newest temporal zone: cybertime.

Time, Chronology, and Periodization in History

Masayuki Sato, University of Yamanashi, Kōfu, Yamanashi, Japan

Abstract

Homo sapiens is the only species on Earth that is equipped to look back on its past consciously. The past, however, is chaotic. Nevertheless, it is the peculiar ability of humankind, as *Homo historicus*, to put some kind of order on this chaos, making it understandable. It is this conscious looking back to the past that identifies *H. sapiens* as human. The most important element in bringing order to the chaos of the past is a concept of time. Time is a human invention rendering chaos intelligible, rather than something that exists in itself. Among various notions of time, chronology and periodization are the most closely connected with organizing of our past. Without these conceptual inventions, there would be no way of organizing our past as history.

Homo sapiens is the only species on Earth that is equipped to look back on its past consciously. The past, however, is chaotic. Nevertheless, it is the peculiar ability of humankind, as *Homo historicus*, to order this chaos, making it understandable. It is this conscious looking back to the past that identifies *H. sapiens* as human.

The most important element in bringing order to the past is a concept of time. Rather than positing time as existing in itself, it may profitably be viewed as a transcendental condition that renders the largely unstructured flux of the past intelligible. Among the various notions of time, chronology, and periodization are the most closely connected with the organization of our past. Without these conceptual inventions, there would be no way of organizing our past as history.

Chronology is a dating system, or a system of reckoning a series of years from a starting point (year), which gives an era a theoretical definition. In this respect, chronology should be distinguished from a calendar, which is defined as a system of fixing the year, month, and date (Blackburn and Holford-Strevens, 1999).

Periodization is a form of historiological cognition proposed by the human mind for making the past intelligible and meaningful by dividing the collective past into compartments along time (Croce, 1916(1960)).

On the one hand, chronology is different from periodization in that it is used by a group of people for practical purposes, mainly for counting years. Those who try to make sense of history through rendering the past retrospectively intelligible, on the other hand, mostly use periodization. It is of no practical use for counting time.

Chronology, therefore, exists in these terms mainly for constructing time, and periodization for dividing time. However, further inquiry reveals that chronology also acts to divide time by creating a starting point for a new era, e.g., regnal years, Christian chronology, and East Asian era names. On the other hand, the very act of periodizing of the past effectively constructs a new time by inventing an arbitrary starting point, though these times are not used by people in everyday life, as for example the 'Victorian period' or the 'Middle Ages'.

Four Aspects of Time in History

Time in history will be considered from the following four viewpoints: the three types of time; the relation between linear time and cyclical time; the relation between what I call the stream of time and the stack of time; and finally, what governs time.

Three Types of Time

Time can be classified into three categories: natural time, human time, and metaphysical time. Natural time is a reflection of natural cycles as seasons, human life, etc. Human time is what *H. sapiens* has invented to make the remembered past intelligible and comprehensible, and consists of such schemes as chronology and periodization. Metaphysical time, as proposed by philosophers of history, is what *H. sapiens* has created to make the remembered past meaningful beyond the experience of a single human.

Linear Time and Cyclical Time

Among Western historians, time in history has been discussed in terms of the established dichotomy of linear and cyclical time. There is a consensus among them that a culture based on nonlinear time would not be able to construct historical thinking. India, for example, has sometimes been described as being without a 'historical mind', because it was a culture that lacked linear time and lived in cyclical time. That linear time that is necessary for the rise of the historical mind has been accepted by a large number of European philosophers, although it was contested by Giambattista Vico, Friedrich Nietzsche, Oswald Spengler, and others. This assumption is also contradicted by the historiographical accomplishments of East Asia, which led the premodern world both in the quality and quantity of its historical production, despite the fact that linear conceptions of time were relatively weak. They were, however, not lacking altogether. Even ancient Indian genealogies inscribed on tombstones and monuments show a richness of linear conceptions of time. Archeological remains discovered in ancient Mesoamerican civilizations also testify to the employment of linear time (Feldherr and Hardy, 2011).

Stream of Time and Stack of Time

The examination of what constitutes linear time will lead us to a comprehensive understanding of the nature of historical time.

Linear time proceeds from the viewpoint that time is ordered sequentially like a stream of water in the river. This time is recorded by a sequence of numbers, as is characteristic in the Western (Christian) way of counting years, and it has given us a view of historical time as proceeding in a linear fashion.

Along with this idea, a frame of regnal years, or East Asian era names (a metamorphosis of regnal years) has been widely used. This implies a view of time as being stacked like a pile of bricks, rather than flowing like water in the river. This image of time reflects a fundamental stratum of our consciousness, as when we look back into the past, and remember 'my school days', 'our Tokyo period', or 'between the wars'.

The Western cultures that now dominate the modern world extended their mode of historical thinking based on linear time across the globe, often imposing their sense of time on others as if such a scheme were something universal. Recent studies have shown, however, that a sense of linear time is culturally comparatively limited, while compartmentalized time is in many ways more fundamental and widespread (Sato, 1991). Cross-cultural observations seem to indicate that 'stack time' actually constitutes the most common sense of historical time. In the East Asian context, in particular, varied combinations of compartmentalized time have been developed. That linear time played such an important role in European circumstances is thus probably the result of a necessity for periodization in the development of historical studies.

Time Belongs to the Supreme Nominal Power

Throughout history conceptions of time were regulated and authorized by those who possessed the supreme nominal power. Time was set and controlled by the central authority.

Historically, the powers that governed human time can be divided into two different types: religious power and political power. Religious powers in the Western Hemisphere, in particular Christianity, Judaism, and Islam have controlled time, in broad terms. However, time in the Eastern Hemisphere has been governed by political power.

In China, time belonged to the emperor. A new dynasty and a new emperor declared the enthronement of a new power by proclaiming a new era name and a new calendar. The Chinese emperor confirmed the establishment of his power by the introduction of his time. In Japan, since the seventh century, time also belonged to the emperor. It was the emperor's duty and prerogative to declare a new era's name, a privilege retained even during military rule. Even the Tokugawa shogunate, despite its military and political might, could not deprive the Emperor of this privilege. After World War II, the Christian chronology–based time came into use in East Asia, along with Greenwich Mean Time. However, Japan and Taiwan still employ the era name system officially. North Korea introduced an era name system in 1997, and the new era name was 'Juche' (Autonomy), to commemorate the late Kim Il-Sung. The era started retroactively from his birth in 1921.

Western time based on Christian chronology and universal time now occupies the role of a common time in the world. The introduction of Christian chronology made the practice of a world historiography possible by giving a synchronicity to the history of the world. The time that now governs the world belongs to the supreme world power called 'globalization'. The expansion of the Internet communications necessitates a World common time. A similar situation was found in early modern Europe. Problems arose for merchants in setting contract dates between different countries that used various regnal years and dating systems. As a result merchants were among the first to promote the use of a common Christian chronology strongly (Lippincott et al., 2000).

Chronology

Chronology can be classified into the three types according to their features: linear chronology, stratified chronology, and cyclical chronology. The major issue of chronology focuses on the question of why, in spite of its defects, the Christian chronology was able to become a common system.

Linear Chronology

Linear chronology is a system of reckoning a series of years in a straight line from a starting point (year) of an era. Jewish chronology, Christian chronology, Islamic chronology, Buddhist chronology, etc., all belong to this type of chronology.

Linear chronology consists of two types: one counts the years serially from the starting year toward the future, and the other counts years both backward and forward from the starting year. The latter idea of reckoning years both to the future and to the past endlessly is only found in Christian chronology.

This idea of a single-era system of counting years is found all over the world. In ancient times, Mesopotamian chronology began with the accession of Nabonassar in 747 BC, and Roman chronology reckoned years from the foundation of Rome in 753 BC. Jews have counted years from the foundation of the world (*Anno Mundi*) since the third century.

Dionysius Exiguus, an abbot in Rome in 525, first introduced Christian chronology, as we know it, on the grounds that years should be noted from the incarnation of Jesus Christ, instead of the era of Diocletian, the persecutor of Christians in ancient Rome. Dionysius calculated the birth of Christ as the 753rd year from the foundation of Rome, and made this year the first year of *Anno Domini* (AD). However, it was not until the eleventh century that this chronology began to circulate widely in Europe (Finegan, 1964).

Islamic chronology (the era of the *Hijra*) was instituted by Caliph 'Umar I in 638 by introducing the system of counting years from the *Hijra*, that is the flight of Mohammed from Mecca to Medina on 16 July, 622, the first day of the lunar year. The Islamic chronology is unique among the other linear chronologies in that it is a purely lunar-based chronology, i.e., the year is counted as the cycle of 12 lunar months, not as the revolution of the Earth around the Sun.

Buddhist chronology is now used in some Southeast Asian countries. In Thailand and Cambodia, years are counted from the putative date of the death of the Buddha in 543 BC, while Myanmar employs the date of the introduction of Buddhism in 638 as the first year of their chronology. In India, the government reformed the calendar in 1957 based on the Saka era (starting from 78), and it is now widely used.

At least 10 other single-era linear chronologies have been proposed, including the era of the emperor Huang and the era of Confucius in China, and the era of Tangun in Korea.

Stratified Chronology

Stratified chronology is a system of reckoning years by successively piling eras (sets of years) upon one another in sequence, an idea that originated in the regnal year system. The method of counting years by royal succession has been used throughout the world since ancient times, and it was also used widely in Europe even after Christian chronology was circulated in the sixteenth century. The method of dating by regnal years, though troublesome, satisfies the theoretical requirements of specifying years, and this chronology finds its most significant expression in the era name system of East Asia. The era name system derives its origin from the idea of conferring a significant title to a certain series of years, instead of using simple regnal years. It was first introduced by the emperor Wu of the Han dynasty in China, in 114 BC. The years of his reign were named according to heavenly good omens as 'Founding the First Era', 'The First Light', 'The First Hunting', etc.

This idea of chronology later rippled out in all directions to the countries on China's periphery. It was employed in Vietnam and Korea by the middle of the sixth century, and by the middle of the seventh century, at the latest, it had reached Japan. These East Asian countries on the Chinese periphery took the idea of the era name system but made little use of the Chinese names themselves. When used in tandem with the Chinese sexagesimal cyclical system, the era name system fulfilled its function as a method of reckoning years in East Asia.

East Asia was chronologically under the exclusive dominance of the era name and sexagesimal cycle systems. The era name system was premised on the very existence of Chinese letters as ideographic characters. Ideographic characters made possible the development of the East Asian philosophy of chronology, i.e., that the counting of years is not an act of assigning an ordinal number to a year, but rather that of giving a year a meaningful name.

It originates in the *Weltanschauung* inherent in ideographic characters: that Chinese characters by their very nature assign a meaningful name to every aspect of the world and the era name system could be seen as an extension of this. Assigning a meaningful name to a month was common throughout the world, but outside of East Asia designating a set of years by a single name, was, when it occurred at all, usually a matter of a historian's conception and not of an official or public designation.

For more than 2000 years, until the middle of the twentieth century, this era name system was employed in East Asia, to the virtual exclusion of all other modes of reckoning. The Christian era system was brought into East Asia during the latter half of the nineteenth century as part of Western culture. The system took the place of era names in the subsequent century. Japan, Taiwan, and North Korea still employ the era name system officially, though the Christian era system is widely used as well. It tells us that the idea of reckoning years within the context of meaningful names is deeply rooted and alive in the collective consciousness of East Asian people (Prusek, 1963).

Cyclical Chronology

In addition to the above two types of chronology, cyclical chronologies have long been used all over the world. Well-known examples of these are the chronology by indiction (*indictio*) in early Medieval Europe, and the sexagesimal cycle in East Asia. In this type of chronology, years were given according to their place in the cycle of 15 years (*indictio*), or 60 years (the sexagesimal cycle), the number of the *indictio* or the sexagesimal cycle itself being ignored. They could be called chronologies in the sense that they turned into absolute chronology by giving ordinal numbers to the cycle, in the same way that the Olympic dating system operates. It was also possible to apply such an ordering to the sexagesimal cycle, but it was rarely used in practice. This method may also be called a relative chronology in the sense that it was not used to designate specified years in comparison with an absolute chronology.

The Hindu idea of chronology is cyclical, but it is unique in its philosophy of time in that cosmic cycles of creation and destruction continue indefinitely. In Hinduism, time belongs to the supreme God, and one chronological cycle (*yugas*) is 4 320 000 years (Eliade, 1954).

The Christian Era System as the Common World Chronology

Since the Christian chronology starts from the AD 1, the twenty-first century begins in 2001, not 2000. The concept of zero was not yet known in the West when the Christian chronology was created in the sixth century. Zero came to Europe around the tenth century, from India, via the Islamic countries. In addition it is now believed that there was an error in assigning the year of Jesus' birth, and he was in fact born a few years before the year AD 1.

In spite of these imperfections, we live with a Christian chronology that is now so dominant in worldwide usage that there is no possibility of it being replaced with a new or revised method at any time in the foreseeable future. Christian chronology now occupies the role of a common or neutral chronology in the world. This was theoretically brought into effect by introducing the concept of 'BC' and deciding on the first day of January as New Year's Day; and it had been politically determined by the dominance of Western culture since the nineteenth century.

It is important to inquire here why the invention of 'BC' made the Christian era system the universal chronology. It is because it has the great advantage of locating every historical event on a single time base.

Venerable Bede, in his *Historia ecclesiastica gentis Anglorum* (731), first proposed the idea as *anno igitur ante incarnationem Dominicam* (in the year, therefore, before the incarnation of the Lord). The expression became widely used after the late sixteenth century in a period known as the dispute over Christian chronology. This dispute arose because of disagreements between scholars concerning the period between the Creation and the birth of Christ, and because of inconsistencies between Christian and non-Christian ancient histories, as for example in the differences between the Chinese records and the

Bible. However, since the seventeenth century, the idea of BC has been used widely in Europe.

It should be remembered that BC was first used, not independently, but as an auxiliary chronology to *Anno Mundi*. The secularization of the Christian idea of history was necessary for the exclusive use of BC, which started in the eighteenth century. An early example of the transformation of the Biblical chronology into a secular chronology can be found in Voltaire's *Essai sur les moeurs et l'esprit des nations* (1756), where the concept of BC became an indispensable part of modern chronology.

As a result of the developments in archaeology and geology in the scientific revolution of early modern Europe, the method of counting serially backwards from the birth of Christ proved extremely useful in dealing with the debate over 'the creation of the world'. It was, perhaps, accidental that BC came into such use, since it was originally conceived in order to describe the years between the Biblical Creation and the birth of Christ. It was beyond the imagination of its founders to think of a time 'before the Creation'.

It is a curious irony that this Christian chronology was so suited to tackle the scientific revolution, and it spread itself beyond the boundaries of Christendom. The invention of BC transformed the Christian era system from being a specifically Christian chronology to being one with a universal potential. It is now widely used in non-Christian countries as the main chronology. For example, China officially introduced the Christian chronology as the Common Era (*Kungyuan*) in 1949, in order to become synchronized with the rest of the world. Joseph Needham proposed the idea of chronological expression avoiding the writing of dates as 'BC' and 'AD' by the use of '−' and '+' respectively in his *Science and Civilization in China*, because "such a convention seems also more suitable for civilizations which were never part of Christendom" (Needham, 1966).

The idea of a common chronology is premised on the notion that all peoples, cultures, and nations have their own 'year', which allows the common man to create a balanced sense of history, and acquire the possibility of a free and varied sense of time. Because the reckoning of years is not a mere assignment of numbers in order, but the creation of a cognitive framework for experience and memory, it is in itself an advanced intellectual exercise peculiar to the human species. It is also a political, social, and cultural act of human intelligence (Sato, 1991).

Periodization

Periodization has been practiced since ancient times. Well-known examples are the four metallic ages (gold, silver, bronze, and iron) as introduced by Hesiod in the seventh century BC, Daniel's dream of the four kingdoms and its interpretation (Babylonian, Medo-Persian, Macedonian, and Roman monarchies), the Buddhist idea of the threefold periods (the true law, the reflected law, and the end of the law), and Saint Augustine's proposition of six periods (*infantia*, *pueritia*, *adulescentia*, *iuventus*, *gravitas*, and *senectus*, the last named corresponding to the period from the Christ to the end of time). Each had a fundamental influence on the premodern people in its respective civilization. In the East, it was a matter of primary concern to know when the period of the end of the law started. Similarly, in the West people were eager to know the advent of Doomsday.

An examination of these periodizations shows us that (1) at a very fundamental historical level people employ compartmentalized time and not linear time for their historical thinking, and (2) characteristically a people acquire their historical *raison d'être* using their past to place their present in history.

This article, however, focuses on the periodization that appeared with the rise of modern historical scholarship in the seventeenth century, and has become a major historiographical asset.

Two Types of Periodizing Terms

Time has been worked within two ways, using both continuous time and compartmentalized time.

It is natural and inherent for us to employ compartmentalized time when we look back into the past. In the same way historians in their research invent compartmentalized time in order to give the past a certain unity. Thus compartmentalized time is a natural and indispensable historiographical tool.

Historians have employed compartmentalized time in two fundamentally different ways; one was to use the historically existing compartments, and the other was to invent and retrospectively apply a structure. Dynastic periodizations widely used in the East and the West are typical of the former; however, the latter represented, for example, by Christophus Cellarius, Karl Marx, Fernand Braudel have almost always been created in the West (Braudel, 1980).

Periodization as a Historiological Tool

Periodization is a form of historical understanding, designed as a historiological tool for making the past understandable, intelligible, and meaningful by dividing it into compartments. It was developed largely in the West in the early modern period under the dominance of Christian chronology. More generally speaking, it was to be found in civilizations where linear chronology played a central role, for example Ibn Khaldun's distinction between the *umran badawi* (rural culture) and the *umran hahari* (urban culture).

Periodization became a key feature of Western historiography, which developed into a cognitive discipline by proposing new perspectives and varied interpretations. This contrasts strongly with the East Asian experience. Even though a rich historiographical culture flourished in East Asia for more than 2000 years as a major field of learning, it did not propose the universally applicable type of terminologies used by Western historians. However, East Asian historians employed the combination of many different types of periodization in their written history, such as dynasties, era names, sexagesimal cycles, and periods based on changes in the site of the capital. Modern European history, on the other hand, drew on a long and deep-rooted tradition of annals and chronicles, whose style depended solely on a concept of continuous time.

The various periodizations were essential for their establishing history. Even now, a list of titles of recent works by Western historians reads like an inventory of variously compartmentalized time.

The Christian era system had been in use in the West long before the birth of historiography in modern Europe, at which time the historians took an interest in compartmentalizing the past in order to analyze history. In one sense, it could be viewed as a declaration of independence by modern historiography from such traditional forms as annals and chronicles.

In the 1700s, the word 'century' came into use, signifying that the modern Western mind needed compartmentalized time for thinking about history. In Western historiography such statements as 'the first half of a century', 'the first quarter of a century', or '1930s' are used quite freely and this is a sign that compartmentalized time has become indispensable for looking back upon the past, which cannot be grasped simply by employing absolute years.

To summarize, in the West the idea of a single-era count formed the basis of chronology, i.e., the Christian era system. Given this basis historians employed many different kinds of periodization to compartmentalize time to think about history. By contrast, in East Asia only the compartmentalized time could be found in historiography. Their historiographical style was developed on a stratified or stack-shaped chronology and various other types of compartmentalized time. The expansion of modern European historiography, paralleling the global reach of Euro-American military and economic power in the late nineteenth century meant that historians everywhere are now using the technique of using periodization to understand history. *Pensare la storia e certamente periodizzarla* (to think history is certainly to periodize) (Croce, 1916(1960)) is a view now shared by all world historians.

Later development of periodization to incorporate such concepts as the 'feudal period', the 'medieval period', etc. has given rise to the reinterpretation of human history on an international scale. The idea of dividing history into three periods was the first success of the method.

Universality of the Tripartite Periodization

The universal acceptance of a tripartite periodization: ancient, medieval, and modern has had a fundamental influence on the development of world historiographies.

This threefold periodization was first employed by Georg Hornius, a Dutch historian in his *Arca Noae* (1666), and became widely known later through Christophorus Cellarius, a German historian, in his *Historia nova, hoc est XVI et XVII saeculorum* (1696). With the transmission of modern German historical scholarship it spread across the world two centuries later and has been taken for granted as a global standard since then.

This threefold periodization found universal acceptance for two reasons: (1) the terminologies were almost free from religious connotations and Euro Christian signs, even though *medium Aevum* was originally a theological notion, and (2) it included a universal attitude toward the past by instituting a negative period between the glorious past and the contemporary period.

There is still no agreement in deciding on the exact border years among the ancient, the medieval, and the modern. Professional historians have concentrated later on subdivisions of the three periods. This lack of consensus encouraged disputes among the historians of the world. As a result of this debate and the development of social and economic histories it became apparent that the very idea of border years was out-of-date.

Periodization as a way of historical thinking was developed still further by new proposals for dividing the human past. The most influential of these ideas of periodization were the 'feudal period', pioneered by Henri Pirenne, and the 'capitalist period', widely used by Marxist historians. These periodizations were discussed in the historical contexts not only of Europe, but also of the non-Western world, especially China, India, and Japan.

After World War II, Fernand Braudel published a new idea of periodization in 1949, by proposing the notion of three different rhythms of history. The *long dureé* (the long duration) became the main concern of postwar historians. This structural periodization spread over the world on the wind of social history, and became the shared perspective of the historians of the world.

Visualization of Historical Time, Chronology, and Periodization

History is the science of making our chaotic past intelligible and meaningful through a variety of interpretive and structural techniques; among these, the imposition of a systematic notion of time has proved to be one of the most important. The construction of time lines, royal lines, genealogies, chronicles, annals, and historical tables, which have developed since ancient times, helps to form our historical knowledge and mind. The further necessity of knowing the synchronicity of the plural lines was the first step toward reaching a historical consciousness. Peoples have proposed a variety of ideas to synchronize the different times of human history.

The synchronizing of historical events that happened in different places and times can be viewed as the singular most distinguished achievement in the historical consciousness of the human mind. This is reflected in the construction of chronological tables or historical tables.

It is necessary here to distinguish chronological tables from annals and chronicles; they have very different purposes. Annals and chronicles attach importance to the content they record; on the other hand, chronological tables stress the date or sequence of historical events.

The chronological table gives us a visualized temporal image of our past, in the same way that a world atlas shows us a visualized spatial image of the world. It has two important functions. One is to give a bird's eye view of the stream of time in history, the other is to make certain of the synchronicity of historical events in various parts of the world.

In East Asia, the use of chronological tables as a reference for comprehending history was first proposed by Sima Qiam (135–93 BC) in his *Shiji* (Records of the Historian). They can be viewed as the beginning of a consciousness of historical time. He arranged 'the chronological table of the twelve dukes' by separating lines for the events of each of the 12 states. Reading down the columns, one sees what happened in each state in

any given year by using the sexagesimal cycle and regnal years of that state. Reading across the columns, one can see the sequence of historical events for any given state. We could say that he made the table to show us history in both its temporal and spatial contexts.

The development of the chronological table in Europe was effected by choosing Anno Mundi, or Christian chronology, as the key time scale, around which the various historical events were listed.

The historical time-based Christian chronology was already established in Europe by the sixteenth century. However, at that time it was primarily employed in the field of ecclesiastical history. It was not until the eighteenth century that these two chronological methods were unified into Christian chronology. At that time historical events were rewritten in terms of the Christian chronology and thus were synchronized with events in the rest of the world. This synchronicity laid the foundations of a time consciousness capable of giving birth to the modern method of historical thinking. Benjamin Marshall's *Chronological Tables* (1713) is one of the earliest works of this genre. John Blair published *The Chronology and History* (London, 1754), in which he proposed a table of various regnal years in Europe, which was constructed around a time line of years since the birth of Christ. James Bell established the earliest style of modern historical tables in his *A View of Universal History* (London, 1842). Historical tables were disseminated throughout the world through the works of Karl Ploets (1819–81), a German historian (Sato, 1991).

Since the latter half of the nineteenth century, Christian chronology as the historiographical 'standard time' has spread throughout the non-Christian world. This chronology has been established as the pivotal time by which the world creates and maintains the possibility of a synchronicity of the various local historical times. It is only with this temporal foundation that it is possible to write a history of the world.

Time-Space in Geography

Donald G Janelle, University of California, Santa Barbara, CA, USA

Abstract

This article reviews the development of time-space perspectives in geography and exposes linkages between these perspectives and society's prevailing technologies for travel and communication. Special attention is given to the role of information, computation, and visualization technologies that shape the research practices that advance the potential to understand social organization and human activity behavior in a time-space context.

Geographers have always regarded space and time as fundamental attributes of reality. However, significant variations have existed in the meaning associated with these concepts. The independence of space and time – where each concept provides a separate frame of reference for positioning objects and events – is seen in both regional studies and in attempts to cast geography as a purely spatial science. In contrast, the merger of time and space into the singular notion of time-space has for many researchers become the ideal, at least in concept, if not in practice. In large measure, the technologies available at any given time have conditioned the historical transition in philosophical perspectives on time, space, and time-space in geography. Recent developments in data gathering methods linked through computational and information technologies and advanced systems for analysis and visualization (often referred to collectively as cyberinfrastructure) have dramatically altered the prospects for understanding and estimating the impact of space-time processes on human-environment relationships and human behavior (Dijst, 2013; Goodchild, 2013; Richardson, 2013). This raises an intriguing question; How might a truly time-space perspective with complementary supportive tools alter the outlook for geography as an integrative and relevant discipline in the twenty-first century? The following sections explore the transition in time-space thinking in geography and address some of the philosophical and technical challenges in their application to the study of human behavior.

Absolute vs Relative Views of Time and Space

Immanuel Kant (1724–1804), who was less noted for instruction in physical geography at the University of Königsberg than for his broader theory of knowledge, was instrumental in laying a philosophical basis for treating time and space as a priori separate from each other, with absolute dimensions validated through human experience. In contrast to Kant's view, the inseparability of space and time is embraced in the concept of time-space as a single definable dimension of reality, where one cannot have space without time, and vice versa. This perspective, one of the foundations of relativity theory, conceives time-space in relationship to the movement of material objects and to events, an idea dependent for confirmation on significant advances in measurement technologies since the late nineteenth century. Conceptually, the coincidence of time and space is easy to grasp – any object or event simultaneously embraces positions in time and in space (e.g., tossing a ball and observing its flight) – easy to say in the realm of what is observable with our unaided human senses but more challenging as distances increase in geographical space and move beyond our direct senses in nano and cosmic spaces.

From an operational and measurement perspective, researchers often return to the Kantian view, treating the separation of time and space as a practical necessity. Geographers have attempted to work around this difficulty in two principal ways. First, explanatory and descriptive models (e.g., Walter Christaller's central place theory) may be used to consider the human settlement system and human activity patterns at different points in time as a means of detecting historical changes in the spatial character of landscapes and human behavior. Second, researchers may abstract the time dimension of change into periods or stages, sometimes in arbitrary correspondence to the processes being investigated. An example of the latter is the use of census data, where changes might be assessed over a 10-year period, such as population growth within a region between 2000 and 2010. The easy availability of a national census has rendered census data as a pragmatic, although less than ideal, choice for describing and mapping demographic and other patterns of change that shape human behavioral landscapes. However, the implicit assumptions and the limitations of this approach are problematic, especially the representation of continuous and often complex processes as disrupted sequences of snapshots at regular intervals in time and the chunking of space into counties, census tracks, block groups, and blocks. Researchers often skirt this issue altogether by conceptualizing and defining periods of time or stages according to the dominance of certain social circumstances (e.g., the baby-boom period) or of prevailing technologies (e.g., the automobile era). This approach is attractive for description of general processes but in most cases falls short of rigorous analysis in a strictly scientific context.

From Spatial to Time-Spatial Perspectives

Attempts in the 1950s and 1960s to recast geography from a descriptive to a predictive science offer a clear demarcation in the progression of thinking about time-space in geography. In the traditional paradigm of regional descriptive geography, time and space were treated as separate even though attention was given to documenting landscape conditions at different

points in time. Theoretical quantitative geography emerged to counter the descriptive focus of this tradition; nonetheless many researchers retained the separation of time from space in what was termed the exceptionalism of the spatial paradigm. This was most pronounced in the advocacy of Schaefer (1953) and Bunge (1962) for whom geography was a theoretical science in search of spatial morphological laws. However, the merger of geography's theoretical thrust with the practical issues of society necessitated a predictive perspective, one focused more specifically on the mapping of events and related movements across space through time.

From Snapshots to Dynamic Time-Space Conceptualizations of Behavioral Landscapes

Interest in prediction resulted in a shift of emphasis from the depiction and explanation of geographical patterns to that of process identification for the understanding of the dynamics of regional economies and the nature of human spatial behavior. Thus, from a fundamental focus on pure spatial form, attention turned to the movements of objects and to the passage of events through space. Models to simulate urban growth and other phenomena as processes of spatial diffusion represent explicit attempts to mesh the time and space dimensions in geographical research.

Significant statements advancing time-space perspectives are found in Hägerstrand's (1970, 1973) conceptualizations of spatial diffusion and time geography, Janelle's 1968 formulation of time-space convergence (TSC) (see Janelle, 2014), and Harvey's (1990) focus on time-space compression. The time geography, convergence, and compression concepts are discussed in the following sections, especially in relation to rapid changes in the availability of geo-referenced data, live data feeds from remote and embedded environmental sensors, and a plethora of ever-more-sophisticated tools for information gathering, processing, analysis, visualization, and communication.

Time Geography

At the behavioral level, Torsten Hägerstrand's time geography model of society stands out in its attempt to capture the movement and activity participation of people through conceptualization and graphic representation of their space-time locations. The concept of an individual's time-space path captures the continuity of human existence as a directed line (a trajectory) that occupies space and time simultaneously and continuously, depicting a person's activities in space through the temporal cycles of the day or through a lifetime. The inherent Euclidean nature of this space is a consequence of treating time-space as a homogeneous medium for movement, broken up in response to social, environmental, and other constraints that determine who has access to specific spaces at given times and under what circumstances.

Hägerstrand's motivation for a time geography of social activity was to provide tools to assist planners and policy makers in conceptualizing how their decisions influence the spacing and timing of landscapes and services so as to minimize constraints on access to essential and desired resources (e.g., jobs, day care services, health care, schools, and recreation opportunities). His identification of capability, coupling, and authority constraints represents an insightful means of delimiting the geographical limits to an individual's activity patterns over any given period of time. In Hägerstrand's conceptualization, people's access to opportunities is based on their capabilities, such as: their means for moving from one location to another, their ability to free up time and finances for traveling and engaging in activities within a specified time span; their need to interact (couple) with other individuals or physical resources to carry out economic, social, and other transactions; and their ability to perform activities that ascribe to the authority rules, physical boundaries, and fees that govern access to resources and places. For example, the operational hours of public and private facilities (e.g., the library or clinic), entry fees for a concert or sporting event, and ownership rights that control for trespass or public accessibility are instances of authority constraints, often essential to rationalizing investments but restrictive to open participation. Thus, through time geography, the space-time autonomy of individuals or groups is defined by the behavioral options that are accessible in time and space within a local context after consideration of capability, coupling, and authority constraints.

Through graphic representation, Hägerstrand provided a unique means of representing time geography problems and solutions. Figure 1(a) depicts the core elements of the model: a representation of a time-space (shown here in three

Figure 1 Graphic representation of some of the basic elements of time geography: (a) space-time activity paths of individuals A and B; (b) the space-time prism defines the temporal and spatial limits of an individual's activity options for a single day, projected in 2D space as a potential path area (PPA).

dimensions), the space-time paths of individuals A and B over the course of a 24-hour day, and the linking of their separate paths to form an activity bundle (coupling) at a work location. The home base is allocated special significance for allowance of regular sleep, sustenance, and fulfillment of individual and family obligations, whereas employment or schooling activities may be seen as obligatory for acquiring the income and knowledge to function within a society. In Figure 1(b), the path is constrained by the necessity to be at home in the earlier and later parts of the day. At a given travel speed (designated by the slope of the path, and subject to capability and authority constraints), the outer margins of travel distance define the bounds of a space-time prism in which all activities must take place. In geographical space, the confines of activity participation are shown as a potential path area (PPA). More complex patterns could be represented by composite prisms linked by travel paths that result in a series of PPAs. Such graphic representations maybe used to depict a broad range of problems at varying levels of complexity to add clarity to social and planning issues and to possible solutions and outcomes. Examples include documenting temporal patterns in the gender differentiation of urban space, disease contagion, measuring and predicting the likelihood of successful trip outcomes based on the means of travel, equity in accessibility to services in cities, multiscale experiences in physical and virtual worlds, time-geographic strategies of police surveillance to protect vulnerable neighborhoods from burglary activity, trade-offs in telecommuting at household and societal levels, and the implementation of flexible work hours on activity choices, among many others.

Since its formulation in the early 1960s, the adoption of time geography has been constrained for lack of accessible data resources and computational models, but the past decade has seen a significant surge of interest and refinement in time geography theory, with the development of new tools for data acquisition, analysis, and display, especially in facilitating the integration of data from activity diaries and from social networks within geographic information systems (GISs). Some highlights of these developments include:

- Miller's (2005: 17) time geographic measurement theory has contributed "analytical formulations for basic time geography entities and relations, specifically, the space–time path, prism, composite path-prisms, stations, bundling, and intersections" that increase the likelihood of time geography's use within formal computational display systems (e.g., GIS);
- The mapping of opportunity spaces for individual space-time paths draws on refined conceptualizations that allow for variations in travel speeds and for isotropic and anisotropic conditions for travel by Miller and Bridwell (2009); and
- Kwan and Lee (2004) and Chen et al. (2011) provide examples of successful integration of time geography within GIS and other advanced data visualization systems.

These technical achievements help ground time geography as a supportive framework for thinking about and visualizing the role of constraints and facilitators of social and behavioral activities in family life and in other diverse socioeconomic settings tied to the character and conception of home, place, and other behavioral environments related to expressions of human agency. Critiques of time geography have focused on its structural determinism, its overreliance on absolute physical dimensions, and on difficulties for incorporating the emotions and diversity of meanings that accompany human behavior in real geographical spaces and places.

The time geography of everyday life and lifetime transitions at individual and societal levels are subject to changes in the physical frameworks in which human activity occur. The following section gives specific attention to technological transitions in modes of transportation and communication. These are seen as space-adjusting technologies that directly affect the authority, coupling, and capability constraints that link human behavior to the socioeconomic circumstances and opportunities of local, regional, and global environments.

TSC and Human Extensibility

The TSC concept has its origins in the mid-1960s (see Janelle, 2014), in a period of significant transition in transportation and communication technologies – the coming of age of limited access highways in Europe and North America, growth in automobile access, European and Japanese investments in high-speed passenger rail systems, the transition from propeller aircraft to jet and supersonic passenger planes for transcontinental and transoceanic flights, and expanding access to television and telephones – all contributing to a discussion of life in a shrinking world. TSC was an attempt to measure this shrinkage and to assess its impact on settlement systems and on the competitive prospects of places in regional and global economies. It is a measure of change in the effort required to overcome distance. Generally, TSC is defined as the average rate of decline in travel time between two places or among sets of places over a specific time period. For example, owing to innovations that span stagecoach travel to automobiles on limited access highways or to express rail, Boston and New York have approached each other at an average annual rate of about 20 min per year between the years 1800 and 2010. Interestingly, these cities converged at an average of about 80 min per year in the period 1800–1830 as a result of innovation in stagecoach technologies and logistics but only 1.2 min per year via automobiles from 1920 to 2010. In contrast to convergence, the parallel concept of time-space divergence provides for the tangible measurement of increases in separation between places that result from traffic congestion and failure to maintain infrastructure, especially in urban regions.

Implicit in the convergence–divergence viewpoint is the recognition that physical points (places on the earth) are in relative motion with respect to one another whenever functional measures (such as travel time and cost) are used as distance metrics. Because levels of investment in transportation and communication technologies are not uniform across space, some places converge much more rapidly with the remainder of the settlement system than do others. Some places, bypassed by modern space-adjusting technologies, will diverge; others will converge or diverge,

contingent on the alterations of transport infrastructure and service provision (for instance, abandonment of air and bus services on selected routes can counter the advantages of a new highway that provides convergence gains only for those with automobiles). Variations in the set of rates that define convergence among all possible pairs of places create a nonhomogeneous time-space that is relative and dependent on the inferred movement of places with respect to one another. In this time-space, places are seen to compete in their quest for comparative gains in accessibility over other places, thereby deriving advantages for attracting economic and other opportunities.

TSC is analogous to the physical concept of velocity and purports to assess the earth-shrinking impact of technological investments to overcoming distance. As a time rate of change in travel time over historical time, it is a metaconcept, abstracted and knowable only through measurement. The structure of the resulting space maybe seen as the frame of reference for human activities in a time geography context, but this framework is constantly in flux and is not describable in terms of Euclidean geometry. Even though this abstraction of reality may not be recognized intuitively, the time-space convergence–divergence process embraces explicit recognition of its social origins as the result of deliberative innovation through investment decisions. It is this human behavioral response to TSC that reshapes the space of human geography. Yet, there is also reciprocity in this process, whereby the existing spatial structure of society also influences emergent patterns of investment to encourage TSC (a form of positive reinforcement). Such investments often reflect the hierarchical positioning of places and their comparative power to influence patterns of convergence among places in regional and global economic systems.

From the perspective of individuals and social groupings, opportunities to take advantage of transportation and telecommunication innovations are dependent on income, education, and social or professional networks that contribute to variations in the potential extensibility of people and places. Human extensibility is an affordance made possible by TSC (Janelle, 1973). It refers to the ability of individuals or agencies to extend their influence and presence over space and through time to distant locations via media and other means of influence over human resources. Such capabilities depend on one's socioeconomic situation and connectivity to the broader world.

Human extensibility parallels the construct of time-space distanciation as advanced in Giddens's (1984) structuration theory. Together, these concepts pose questions regarding the closure or spatial boundedness of human societies and systems. Adams (1995), Kwan (2000), Shaw and Yu (2009), and Buliung (2011) have illustrated how time geography offers a useful means of conceptualizing and documenting the role of communication and information technologies in differentiating processes of human extensibility for various subpopulations at local through global scales. They also bring forward issues concerning the differential abilities of individuals, firms, nations, and other forms of human agency to reach beyond their physical locations to shape possibilities for human livelihood elsewhere. Such discrepancies led Harvey (1990) to advance yet another conception of time-space – time-space compression – a concept rooted in the historical materialism of the political economy.

Time-Space Compression

David Harvey's notion of time-space compression provides a compelling rationale for imbuing time-space with social content and experiential meaning. This is brought about by attempts within Capitalism to extract as much surplus value per unit of time as possible. Although annihilation of space through time is analogous to TSC, the broad implications of compression may be less amenable to direct measurement. Use of the term compression captures the general acceleration of all kinds of events that intensify the turnover of capital and that implode on human existence as substantive levels of stress. Furthermore, in Harvey's interpretation, the transcendence of global capital over local domains thrives on shortened time horizons and on the ability to eradicate distance as an inhibitor to exchange and dominance. The ability of capital to shift resources to different places easily, and often with impunity to the disruption of life at the local scale, suggests that time-space compression may denigrate the importance of place in human society. It is in the inherent mobility and speed of such possible actions that time-space compression challenges any attempts to define the time-space nature of society too rigidly, a theme that Warf (2008) expands upon.

Spatiotemporal Analysis and Cyberinfrastructure

Empirical documentation and hypothesis testing, as well as more humanistic social interpretation, have entered a new stage of early twenty-first century technological prowess for acquiring, generating, searching, integrating, and distributing information about human activity behavior in a time-space context. This cyber-spatial infrastructure incorporates the georeferencing capabilities of global positioning systems (GPSs) and cell tower triangulation to log locations continuously to a meter resolution or less, the ability to capture and/or disseminate information collected through mobile and fixed-location sensors via ICT-based smart handheld phones and wearable instruments, and to draw upon an explosion in the sets of services offered through the Internet. Such a suite of tools is already within the possession of a sizable proportion of the human population and is expanding rapidly; these technologies are the backbone of location-based services – usually offered through private firms and governments that capture and disseminate information based on an individual's location at a given time. Related services include near real-time traffic reports based on the aggregation of cell phone GPS signals, strategically positioned cameras, and other sensors of traffic streams on highways; navigation aids for vehicles, pedestrians, and cyclists; access to maps and satellite imagery based on where one is located, and the ability to know if friends and associates or specific kinds of facilities are located nearby; the means to share correspondence and photographs with specific individuals or networks of friends and associates

via Internet-based social networks; the opportunity to store digital resources of all kinds on large computer servers (the cloud) for safekeeping and future accessibility and for sharing selectively in a secure environment; and, through big-data initiatives, the ability to link data (massive amounts of data – think petabytes) from diverse data providers (Goodchild, 2013; Richardson, 2013).

In the context of research use by scholars and planners, this cyber-spatial infrastructure provides capabilities for monitoring behavioral spaces, for analyzing the social ecologies of place, and for creating dynamic spatial demographies of local regions. Such infrastructure can be used to promote communities of interest at local, regional, and global scales; enhance emergency responses through timely and detailed locationally sensitive information; and accommodate the creation of significant new data resources through volunteered geographic information (Goodchild, 2007). Places are of particular interest to geographers and provide a convenient base for linking other data sources (e.g., social media). However, understanding the origins and reliability of such sources and managing their storage and access entail daunting technical challenges to ensure security, interoperability across software and hardware platforms, and ease of use.

Aside from data, an issue that has hindered broad application of time-space perspectives in the social and behavioral sciences has been the difficulty inherent in representing the underlying complexity of human organization of space through time. But increasingly, integration of space-time analyses and modeling within the frameworks of dynamic mapping, cartographic visualization, and GIS suggest that display technologies are catching up with the long-standing needs of social and behavioral scientists to make effective use of new data resources to provide empirical assessment of alternative theoretical constructs. Advances in agent-based modeling and microsimulation, network analysis, and digital animation are offering new analytical and display methodologies for conveying socioeconomic and behavioral processes for both research and education. The development of virtual globes, such as Google Earth (which features both reasonably current and historical map and imagery coverage), offers opportunities for exploratory learning activities through time-line-based views of current and past landscapes – locally, domestically, and internationally. News media have jumped on the bandwagon of using maps and animated spatial and time-spatial representations to inform the public about events and processes of general public interest – storm tracks, election projections, disease transmission, migration, demographic change, and urban growth, to name a few. A new era has emerged for temporal-spatial thinking for social science researchers and for society.

Summation: Time-Space in Geography and the Humanist Challenge

Transformations in how time and space are viewed and integrated into research and education have been closely linked to the prevailing technologies for acquiring, processing, and disseminating information. This is evident in how people and societies have employed ICT and transportation advances to interact at expanded geographical scales. These technological shifts have always posed opportunities and fundamental challenges for how geographers and other scholars interpret the meaning of place in everyday life and how they integrate these interpretations within theoretical and decision-making frameworks. For example, do the meanings of space and the meanings of time suggest anything beyond their relationship to one another as seen through technologically and socially enabled and continually changing perspectives of time-space?

The theoretical grounding for answering the above question rests, in part, on the ability of researchers to use the emerging tools of analytical representation in their descriptions, analyses, and interpretations. At the same time, answers rest fundamentally on being able to recognize humanist qualities in the nature of time-space. The humanization of time-space acknowledges its relativity to different value systems, recognizes its manifold possible metrics, and is able to relate these to human thought processes and experiences. Casting time-space in this manner draws on past formulations and opens the realm of possible investigations to include analytical time-space prediction as well as research formulations grounded in the approaches of critical science and critical social theory.

This takes us back to the question posed at the outset of this article. How might a truly time-space perspective with complementary supportive tools alter the outlook for geography as an integrative and relevant discipline in the twenty-first century? A definitive answer would be risky, but maybe it is safe to speculate that widespread space-time representation of human and natural processes will be tempered by adjudication over fundamental questions regarding the value of privacy and confidentiality. Geography is clearly part of and engaged in such a debate. For geographers and other social and behavioral scientists, the promise of cyberinfrastructure technologies requires equal attention to the important issues regarding the sensitivity of information, protection of confidentiality, and privacy rights (including locational privacy) that cast concern over the social costs associated with advances in space-time information access and search capabilities.

Geography as a discipline is positioned in both the technical worlds of GIScience and cyber-spatial infrastructure and in the humanistic worlds that critically question the implications of these developments for human well-being. Through the integrative roles of theory that address social matters in a time-space perspective and through research tools that are inherently well suited to integrate information spatially (e.g., GIS and cartography), a geography that takes advantage of new technologies to focus on movement and transition, data linkage, interactivity, and animation is well positioned to build connections across knowledge domains to enhance our understanding of the complex space-time transformations that impact human interactions at local through global scales.

Tocqueville, Alexis de (1805–59)

Bernard Valade, Paris Descartes University, Paris, France

Published by Elsevier Ltd.

Abstract

This article presents the life and work of the French writer and politician – mainly focusing on his two most important works, *Democracy in America* and *The Ancient Regime and the Revolution*. B. Valade underscores the originality and richness of Tocqueville's approach and contribution. From a methodological point of view, Tocqueville innovatively used the comparative method and laid the ground for what later was called the methodological individualism. From a theoretical point of view, he laid the foundations of the sociology of intellectuals, of social movements, and of social change. His thought on the democratic mentality, political passions, and tensions between freedom and equality makes proof of a remarkable modernity.

Tocqueville, Alexis de, a French writer and politician, born in Paris on 29 July 1805; died in Cannes on 16 April 1859. Born into an aristocratic background, but free of any resentment, he never ceased to examine the revolutionary process which had been set in motion in 1789. A great traveler, an observer of American democracy, and an analyst of the Ancien Régime in France, he was also a deputy under the Second Republic. His name is associated with a contemplation of the origin and future of democratic society, as well as with a method – comparativism – which was applied spontaneously in his two major works, *De la Démocratie en Amérique* (Democracy in America) (1835–40), and *L'Ancien Régime et la Révolution* (The Ancien Régime and the Revolution) (1856), both of which made their author into a central figure in social science.

The Unity of a Process

Born into a family of very old Norman nobility, Tocqueville first studied philosophy and rhetoric at the Collège Royal in Metz, then law in Paris. In 1827, he was appointed to the judiciary and became a probationary judge at Versailles. Throughout the restoration, he took part in the bitter struggle which set the old aristocracy, enclosed in its traditions, against the new France, led by the middle classes. After the revolution of 1830, and having sworn – not without hesitation – the oath of allegiance to Louis-Philippe, he gave himself plenty of room as far as events were concerned by requesting a commission to conduct a survey into the American penitentiary system. This trip (April 1831–February 1832), undertaken with his friend Gustave de Beaumont, resulted first in a report entitled *Du Système pénitentiaire aux Etats-Unis et de son application en France (On the penitentiary system in the United States and its application in France)* (1833), then the first two volumes of *De la Démocratie en Amérique (Democracy in America)* (1835), and finally what is known as the *Seconde Démocratie (Second Democracy)* (1840). The success of the first part of this work was enough to establish his reputation; in 1838 he was elected to the Academy of Moral and Political Sciences and, 3 years later, he entered the Académie française.

Tocqueville's liking for philosophical reflection did not cancel out his sense of political action. Elected to the Chamber of Deputies in 1839, and reelected several times in his Valognes constituency, he committed himself resolutely to the parliamentary path on the side of the constitutional opposition. On 27 January, in a speech with a prophetic note, he announced the revolution which was to break out 1 month later. After the February Days, he was witness to the clashes of 23–26 June 1848 which put 'the haves' at odds with the 'have-nots.' His *Souvenirs (Recollections)* (1951–to date, vol. XII) relate what this 'great battle waged in Paris' was like. A short-lived Minister for Foreign Affairs under the Prince President of the Second Republic, Tocqueville was returned to his studies for good with the coup d'État of 2 December 1851. *L'Ancien Régime et la Révolution (The Ancien Regime and the Revolution)* appeared in 1856, the second great work which its author was anticipating expanding when tuberculosis cut short his life. He died on 16 April 1859 in Cannes.

Tocqueville's work – which comprises the two great texts of 1835/40 and 1856, the *Recollections*, various papers, speeches, and reports, as well as a vast correspondence – draws its unity from the constant questioning which inspired it: why since 1789, in 1830, and then in 1848, was it always the *same* revolution which starts up again? The unity of the work also stems from the method adopted in order to understand the repetition – in Europe, and in France in particular – of the revolutionary process. Its comparative method, not systematized, but rather applied spontaneously, allowed it to avoid the perils that Eurocentricity and sociocentricity are denounced for today. "Whoever has only studied and seen France will understand nothing of the French Revolution" (1951–to date, vol. II, 1, p. 94). It was therefore without being obsessed with one singular case, and being free of all aristocratic prejudice, that Alexis de Tocqueville set about penetrating the essence of democratic society; by combining 'holism' and 'individualism,' he posited a diagnosis along with a prognosis on modern society whose value and validity were only recognized much later.

In Search of Democracy

"It is not only in order to satisfy curiosity – however legitimate – that I examined America," Tocqueville wrote "I wanted to find any lessons there from which we might profit […] I confess that in America I saw more than just America; I sought an image of democracy itself, its tendencies, its character, its prejudices, its

passions. I wanted to become acquainted with it, if only at least to know what we should hope or fear from it" (1951–to date, vol. I, 1, p. 11). With this definition, the Tocquevillian project was set out as an effort to understand a 'social state' and, secondarily, a political regime. If the first readers of the 1835 work were attracted to the evocation of exotic locations, they were rather more invited to turn the American mirror upon themselves. Three years later, they were to see a different image of democracy which was less suited to charming them.

Tocqueville's confessed search was not, in fact, separable from the recognition of a tendency – considered from the outset irresistible and irreversible – which was specific to modern societies: the march toward the equalization of conditions. Behind the analyses which were put forward, the contrast between aristocratic society and democratic society operated in a virtually permanent state, and it was the transition from the traditional order to the new arrangements in human relations that Tocqueville undertook to study. He approached this by going back to the principles which govern social states and to the institutions which arise out of them. From an early stage, he realized that one principle had to dominate and that the government which was called mixed, that is, which united an aristocratic element with a democratic one, was merely an idle fantasy. The English monarchy, with its strongly dominant aristocratic character, was still able to pass for the model of government; but it was the American system which was called upon to become the model for modern nations. Equally, Tocqueville also developed an 'ideal type' for democratic society, based on the equality of conditions and set against an aristocratic society founded on the hierarchy of status.

If the paths leading to democracy are marked out in different ways, "the great advantage of Americans is to have arrived [there] without having to undergo democratic revolutions, and to have been born equal rather than having to become it." While examining the customs – defined as "the moral and intellectual state of a people" – of Americans, Tocqueville assigned their foundation to a fully accepted equality of conditions (1951–to date, vol. 1, p. 300). In the United States, democracy was in some way 'natural'; its inhabitants had not had to struggle against privileged groups, such as the ones which had resisted in France; they made up an immense middle class within which there was active mobility. Whatever was set down in custom was fostered by institutions – the commune, the jury, and numerous associations. Decentralization and communal democracy allowed citizens to take part in public affairs, and allowed the body social to regulate itself. "Each individual makes up an equal portion of the ruling body, and plays an equal part in the government of the State." The close bond between the political and the social was actually realized in this society, a society which acted upon itself and through itself, since power only existed within it. In this way, the negative effects of individualism were limited. As for the ills which could arise out of equality, liberty provided the cure. In this society where one endeavored to bring people together rather than to set them against each other, and where the most serious social antagonisms were excluded (one found rich people, not a rich class), religion made a powerful contribution to social regulation. Tocqueville clearly highlighted the role of religious beliefs in the bolstering of customs and the upholding of republican institutions. Religion prevented the American citizen 'from imagining everything and forbids him from daring to do everything.' It ordered him to confine himself to the representation of that which was real and to the conception of that which was useful. Through this, the American mentality took shape – pragmatic, not speculative; with a firm grasp of the facts, not prey to ideology.

The general characteristics of the American model are set out clearly in *Democracy in America II*, along with its potential variations such as liberal democracy and revolutionary or democratic despotism; it also includes the amendment to the relationship between the passion for liberty and the passion for equality. Individualism – the childhood illness of democracy – is defined in this work as "a deliberate and peaceful feeling which inclines each citizen to isolate himself from the mass of his fellow men and to withdraw from his family and friends. In this way, after having created for himself a small-scale society for his own benefit, he readily leaves wider society to itself" (1951–to date, vol. I, 2, p. 105). In *The Ancien Regime and the Revolution* one again finds the threat this represents illustrated in the case of France, and the dangers signaled in 1840 which were brought up to date by the comparative analysis of the passions of democracy and of revolution. Another model, this time continental, was in place at the time and was in a way the negative of the American model.

The Analysis of Social Change

"What strikes the European who travels through the United States," Tocqueville noted in *Democracy in America I*, "is the absence of what we call government or administration" (1951–to date, vol. I, 1, p. 69). In 1840, he further drew attention to his initial observation: "Wherever, at the head of a new venture, you see the government in France and a nobleman in England, in America you can be sure to find an association" (1951–to date, I, 2, p. 113). If it was true that a good government was one which taught its citizens to manage without it, this was not working in France. The backdrop to the 1856 work, which links the interpretation of an historical crisis with a theory of social change, was provided by feudalism and its networks of dependence and solidarity where masters and servants were united by reciprocal services. It was this system, social and political, with its intermediary groups, corporations, village communities, provincial assemblies, and so on, that the French monarchy had set about destroying by means of administrative centralization. No one benefited from it; neither the nobleman whose preeminence was affected, nor the bourgeois whose vanity was wounded, nor the ordinary man who still remained the underling. Discontent was universal.

By suppressing the intermediary bodies, by condemning the nobility – stripped of its function and devitalized – to appearing merely as the ornament of despotism, while at the same time encouraging the emergence of new elites but without satisfying their statutory ambitions, royalty had converted an organic whole where each individual was bound to a group into an homogenous mass oscillating between apathy and demand, submission and subversion. Such was the new social state: "men, no longer being bound to each other by any bond of caste, class, corporation, or family, are only too inclined to concern themselves with their own individual interests and too prone to considering only themselves and to withdrawing into a state of narrow individualism where every political virtue is stifled." Thus, centralization, the restriction of liberties, and

the deterioration of public life combine forces. In this way, equality leads to despotism, since it is no longer built on liberty or on participation in communal affairs.

The explanatory variations that Tocqueville identifies therefore relate, as in the 1835/40 work, to characteristic customs, institutions, and circumstances. In the process which they deal with, the revolution no longer appears as a rupture; the terror had only prolonged the process of state centralization which had been initiated earlier. There was, in reality, a continuity between royal absolutism, revolutionary Jacobinism, and imperial politics. In the process in question, religion had also played an important role by virtue of the universalist dimension presented by Catholicism. At the same time, the revolution – itself preaching the abolition of privilege and the equalization of conditions, had "itself become a kind of new religion, an imperfect religion" (1951–to date, vol. II, 1, p. 89). As a result of this, Tocqueville was in no doubt that "all the Revolution did would have been done without it; it was only a violent and hasty process with whose help the political state was adapted to the social state, the deeds to the ideas, and the laws to the customs" (1951–to date, vol. II, 1, p. 66).

One should take note of the manner in which Tocqueville analyzes the social conflicts and their origins and exacerbation. They were born in eighteenth century France in a short period of economic recession following a long phase of general prosperity. It was therefore not increased poverty which triggered off the conflicts, nor was it the weight of former coercive institutions which were the cause. The revolution "did not break out in the regions where these institutions were better preserved and their discomfort and rigor felt most acutely by the people, but on the contrary in those regions where they were felt the least, in such a way that their yoke had seemed all the more unbearable precisely where it was the least heavy" (1951–to date, vol. II, 1, p. 99). It is a question here of situations that one analyzes today in terms of relative frustrations. Tocqueville recognized them perfectly in the case of the emancipation of the peasantry, just as he had in the case of the ascendancy of the bourgeoisie. They made two strongly felt passions explosive: one was "the violent and inextinguishable hatred of inequality"; the other "more recent and less deep-rooted" led individuals "to want to live not only equally, but also freely."

These were the passions which the *philosophes* of the enlightenment had stirred up. They provided a theoretical framework for social protest by showing the necessity of replacing traditional habits with new rules. Far removed from the affairs of state, with no practical experience and therefore inclined to conceive of 'general and abstract theories in government matters,' men of letters undertook to found cloud cuckoo land. Vain debates of ideas took the place of public life: "Political life was violently driven back into literature, and writers, taking the direction of public opinion in hand, found themselves from one moment to the next holding those positions which the leaders of political parties usually occupied in free countries" (1951–to date, vol. II, 1, p. 196). With this observation, Tocqueville paved the way to a sociology of intellectuals.

The Originality of the Contribution

The author of *Democracy in America* was hailed by his contemporaries as a new Montesquieu. The historians of the nineteenth century saw in *The Ancien Regime and the Revolution* a major contribution to historiography. If the glory of Tocqueville knew no eclipse in the United States, his work did in France, however, fall into a kind of oblivion from which it did not emerge until after World War II. It is to Raymond Aron (1967) and André Jardin (1984) – who actively worked on the publication of the *Oeuvres Complètes (Complete Works)* – as well as to Jean-Claude Lamberti (1970, 1983) – the author of the first state-commissioned thesis on Tocqueville – that one principally owes the renewal of interest in a work which from then on took its place among the classic works of sociology. There are many reasons for this long purgatory. Tocqueville was not a maker of systems as one so likes in France; he appeared as the champion of liberalism at a time when this current of thought was being strongly denounced; nor did his interpretation of the French Revolution seem ideologically sound; and then his way of thinking seemed to come under a mixed genre of headings – political philosophy, philosophy of history, and general sociology.

The reasons for Tocqueville's return are by no means separable from the turnaround in the intellectual climate which took effect in the last two decades of the twentieth century. The new tendencies are well known – the decline of hypersocialized conceptions of the individual; the freeing of collective memory previously marked by the rupture of revolution; and the loosening in particular of the vice of monocausal determinism. On the latter, the *Recollections* give this opinion which is consistent with the orientation of the social sciences at the beginning of the twenty-first century: "I, for my part, hate these absolute systems, which make all the events of history dependent on great first causes, each one being linked to the other by a chain of inevitability, and which, as it were, remove men from the history of mankind" (1951–to date, vol. XII, p. 84). The social protagonists are restored with a power of deliberation and decision, the choice of strategies, and a certain amount of room for maneuver through methodological individualism. They have 'good reasons,' as Raymond Boudon (1977) definitively emphasized, to act as they do, and it was these reasons which, in concrete situations, Tocqueville attempted to bring to light.

This writer was original and modern first and foremost through his method of implementation; it brings together observations, comparisons in space and time, and generalizations; it retains the significant fact without losing sight of the point of view of the collective whole; and the investigation which it guides is situated both on the macrosociological as well as the microsociological level. The rational reconstruction of the significance, in the end ascribed to human actions and historical events, is carried out from objective and subjective elements. The protagonists' reasons are integrated into the explanatory schema along with their passions. Tocqueville, in fact, invites his reader to weigh up the importance of the passion factors; he urges him thus to 'imagine' through a sympathetic understanding the fate of the French peasant in the eighteenth century: "Imagine this man's condition and calculate if you can the wealth of hatred and envy which has amassed in his heart" (1951–to date, vol. II, 1, p. 106).

Tocqueville's contribution to social science is also original in the way that it poses problems and formulates questions. Why, it is asked in the *Mémoire sur le pauperisme (On pauperism)*

(1835), are the countries which appear to be the most poverty-stricken the ones which, in reality, have the lowest number of inhabitants? And why, inversely, is a section of the population of the opulent nations forced to have recourse to the help of other people in order to live? A comparison between Portugal – where poverty was hardly to be seen because the responsibility was assumed by the networks of traditional solidarity – and England – whose social regulations were broken by the Industrial Revolution which created its wealth – provided the answer. It is therefore not simply a question of observing and describing – *Democracy in America* is not a simple monograph resulting from banal field research – but of understanding the social processes arising from 'good questions.'

Tocqueville's way of thinking was modern, in particular because of the subject it was applied to – that is, democracy. A type of entirely new society was establishing itself in the nineteenth century. Emphasizing its principal traits – notably the reign of public opinion – and the dangers it comprised – in particular the tyranny of the majority – Tocqueville assigned its foundation to a dependent work force and the equality of conditions. The development of the egalitarian mentality which accompanies the establishment of democratic society is a source of dissatisfaction that the hope of mobility is not up to appeasing. Inequalities, reduced in one sphere, spring up again elsewhere – there will never be an end to them. Individualism which causes social completeness to disintegrate brings about a displacement of the boundary which separates public space from the private sphere; the latter extends like a zone of retreat where one concern rules: that of material well-being. At the same time, the author of *Democracy in America* 'saw,' in a splendid passage where prophecy and prediction merge the "type of despotism that democratic nations have to fear." This was a vision of a "vast mass of people all alike and all equal," seeking trifling pleasures, all separated from each other, and above whom "rises up an immense guardian power, absolute, intricate, regulated, provident, and gentle" (1951–to date, vol. I, 2, p. 324), which reduces men to the level of children by making them dependent – this tableau really is the Welfare State.

Tocqueville: Past and Present

Current works touching upon different aspects of Tocqueville's work tend to question some of his acknowledged theses in sociology and history of political ideas, as these allow multiple interpretations, in some cases divergent.

In a substantial volume on Tocqueville's work, Lucien Jaume, theoretician of political ideas, elaborates theses contrary to the ones proposed by Jean-Claude Lamberti and Raymond Boudon (Jaume, 2008). Expanding his demonstration around the concepts of authority and sovereignty, Lucien Jaume argues that there is no 'conflict of perspectives' between the two volumes of *Democracy in America*. In this context, the considerations from 1835 on the 'tyranny of the majority' are not to be opposed to the 'soft despotism' of the 'immense and tutelary power' brought up in 1840. This second volume only continued, in a different form, the same thesis on authority, finding the same solution for different problems: the intermediary bodies. Furthermore, these conclusions are different from the ones of Raymond Boudon (2005), who emphasizes the theoretical and heuristic value of the sociology of Tocqueville. According to L. Jaume, there is a place for 'social constrain' in Tocqueville's sociology, which would be fundamentally Durkheimian.

Numerous studies look at the differences and the similarities between Tocqueville's approaches and the ones of the French liberal thinkers, primarily Benjamin Constant and Madame de Staël, but also the doctrinaire school, represented by Pierre-Paul Royer-Collard, Victor de Broglie, François Guizot, and Charles de Rémusat. Lucien Jaume, as well as Aurelian Craiutu worked toward stressing the converging points rather than the differences between Tocqueville and the French liberal thinkers. They did so by comparing mainly the works of Tocqueville and François Guizot, and rather neglecting the integral liberalism of Benjamin Constant, who belongs to a moral and political philosophy not very popular in France.

As mentioned above, the sociological analysis of Raymond Boudon (*Tocqueville for today*, 2005) highlights the modern aspect of Tocqueville's methodology: his objectivism, his insisting on the usefulness of explanations based on comparisons rather than on interpreting social facts, the use of a variety of conditional rules, and the explanation of social facts based on actions meaningful to the social actors. All these elements make Tocqueville a pioneer of the methodological individualism and a visionary, due to the modern touch of his approach, regarding current social phenomena.

In a similar direction as the one approach by Raymond Boudon, the recent work of Jon Elster on Tocqueville (*Alexis de Tocqueville. The first social scientist*, 2009) stresses the scientific aspects of Tocqueville's work relevant for various areas of study such as causal explanations, individual passions and beliefs and interactions on opinion, etc. Jon Elster does not situate Tocqueville's work in its historical moment, but argues, based on a methodological perspective, why Tocqueville is a pioneer in modern game theory, in rational choice theory and in the analysis of collective action.

To conclude, it is important to acknowledge the role of *Revue Tocqueville/Tocqueville Review*, a bilingual journal published since 1979 and coordinated by Henri Mendras for a long period. This journal, currently biannual, dedicates a considerate number of pages to erudite works, to analyses of social change, to comparative studies, mainly between France and the United States, in an interdisciplinary perspective which reflects the spirit and fruitfulness of Tocqueville's oeuvre.

Topographic Maps

Jon H Kaas, Vanderbilt University, Nashville, TN, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Topographic maps in the brain are organized collections of neurons within subcortical nuclei or cortical areas that isomorphically represent the receptors of the eye, skin, or internal ear or the muscles of the body. The order of the representation reflects the order of the activating inputs to the nucleus or cortical area. Such maps are important in mediating the functions of the brain.

Topographic Maps in the Brain

Topographic maps (a representation in a nucleus or cortical area in the brain that is activated by inputs in a pattern that reflects the pattern of the source of the input such as the receptors of the skin or retina) exist throughout brains (Merzenich and Kaas, 1980). They consist of relatively faithful representations of one level of organization at the next level of organization in a hierarchical system (**Figure 1**). Thus, for example, when the arrangement of sensory receptors in the skin, retina, or cochlea projects to a structure in the central nervous system in a manner that preserves the arrangement of the receptors, the activation pattern in the central structure contains a topographic map of the sensory surface. When the first structure activated in the central nervous system with a topographic map of a sensory surface projects to a second structure in a pattern that continues to preserve the orderly arrangement of the receptors on the sensory surface, the second structure is said to also contain a topographic map, and so on over a series of structures (nuclei and then cortical areas in mammals). As structures at one level may project to more than one structure at the next level, the number of topographic maps at subsequent levels of processing may increase. Topographic maps become less precise from each level as termination of axonal arbors spread out and overlap. In part, this tendency is limited by inhibitory neurons at each level, which suppress weak inputs and thereby limit the functional spread. Strictly topographic representations may be further degraded as neurons with similar response properties grouped at higher levels of processing to subdivide nuclei and cortical areas into repeating sets of modules (a smaller subdivision of neocortex within a cortical area that is anatomically and functionally distinct from bordering cortex; they repeat many times within an area, and they are of many functional types) that locally represent different sensory aspects of the same regions of the receptor sheet. Thus, the second visual area, V2, in visual cortex of primates, represents a series of 40–50 small sectors of visual space (matching parts of the two retinas) three times for three different types of processing. Thus, the topographic map is subdivided and becomes more complicated, and less precisely represents the sensory surface. In addition, topographic maps change from one level of processing to the next level, so that they less directly reflect the sensory surface and reflect a computed parameter or dimension, a so-called computational map (Knudsen et al., 1987). For example, auditory receptors are arranged so that they are activated by sound frequencies in an orderly arrangement from high to

Figure 1 A simplified schematic of how axon projections from the receptor distribution on a sensory surface terminate in a topographic pattern in brain stem nuclei, and how this order is maintained over several steps of processing by similar topographic patterns of connections between subsequent nuclei and cortical areas. Due to a divergence of projections from one level to the next, and other factors, neurons at higher levels of processing generally have larger receptive fields, and the topographic pattern is less precise, and it may be altered in other ways.

low frequencies along the line of receptors, but maps of the locations of sounds relative to the listener exist in the brain that are the result of neural computations based on how sounds are differently activated by frequency-matched receptors in the two ears.

In some sense, when the organization of any nucleus (a subcortical structure that has the features of a cortical area) or cortical area (a division of neocortex that is identified by a pattern of activating input and outputs to other parts of the brain, specific functional roles, and structural specializations; they have been considered 'the organs of the brain') globally reflects the organization of the preceding area that provides the activating input, the nucleus or area is considered to have a topographic map of its activating input. In this broader sense, most nuclei and areas are topographically organized.

Topographic patterns also exist between cortical motor areas and the arrangement of nuclei that move body parts. As an example, primary motor cortex in mammals relates in a medial-to-lateral pattern across cortex to a pattern of movements from hindlimb to forelimb to face and then tongue movements, as revealed by electrical stimulation of neurons in cortex to produce movements. Yet, at a local level, the arrangement is not very topographic, as neurons that involve finger movements might alternate with those that are involved in wrist, forearm, or shoulder movements. Thus, for poorly understood functional reasons, the topography of the motor map in regard to produced movements is fractured to form a mosaic of different movement zones (Kaas, 2012).

The Discovery of Sensory and Motor Topographic Maps in the Brain

The existence of topographic maps in the brain was inferred or revealed in various ways. One of the first signs of the existence of such maps came from careful clinical observations of positions with limited small lesions of the brain or a kind of epilepsy that spread over a short period of time. Thus, in 1860s, John Hughlings Jackson, the neurologist, inferred that only the existence of orderly motor and sensory maps in the brain could explain the experiences of patients with epilepsy when a sensation or movement would start at one location on the body, and then expand systematically to include successively more distant body parts. More recently, compelling experimental evidence for such maps came from studies where investigators directly stimulated the brain electrically through electrodes placed at various locations on the surface of the brain of dogs and monkeys, and later human patients during neurosurgery (Penfield and Boldrey, 1937). As human patients were often awake during such procedures, they could also report where sensations were localized during stimulation. With the advent of microelectrodes and recording systems that could record the responsiveness of neurons to sensory stimuli, maps of sensory surfaces were commonly revealed in nonhuman mammals, and in humans during surgery. Now such maps in humans and monkeys can be revealed noninvasively with magnetic resonance imaging of activity-dependent blood flow responses in the brain.

Brain Maps Today

After years of intensive study, a number of conclusions about topographic maps seem justified. (1) The maps are based on topographic patterns of feed-forward axonal connections. The arrangement of these connections can be very precise, but some scatter that is partly suppressed by inhibitory neurons within the maps is usual. (2) Maps with direct inputs from the receptor sheet are highly topographic, but subsequent higher-order maps become progressively less topographic, so that they are only globally topographic. This means that lower-order maps preserve location and other information from the receptors while higher-order areas have more integrative functions. (3) Topographic maps within systems may differ in many ways. For example, the superior colliculus of most mammals represents the complete visual field of the contralateral, but only the contralateral hemifield of that eye, in conjunction with substantial inputs from the ipsilateral eye, in primates. As another example, the massive sensory input from the hand and resulting large representation of the hand in primary somatosensory cortex of most primates disrupts the continuity of the map such that the representation of the thumb adjoins that of the chin. To conform to its elongated shape along the outer border of primary visual cortex, the second visual area, V2, has an almost complete split of its representation of the contralateral visual hemifield into upper and lower field halves. Other disruptions of topography occur as different types of modular organizations occur within representations. Thus, V2 in primates has four fragmented, interdigitated maps of the contralateral visual hemifield. Primary somatosensory cortex in primates isolates small patches of cortex devoted to slowly adapting cutaneous afferents from patches activated by rapidly adapting afferents such that sectors of the same skin are represented twice within the overall topographic map. (4) Higher-order maps may be derived or computed from topographic maps. Thus, a map of auditory space for the location of sounds exists in the midbrain. This map is derived from earlier topographic maps. Most higher-order cortical maps appear to reflect both topographic and computational components. (5) Vertebrates and especially mammals vary in the number of topographic maps in their brains. Mammals have greatly varying amounts of neocortex providing varying amounts of space for maps. All mammals have some topographic maps in cortex, but mammals with large amounts of cortex, especially humans, have more maps. This increases the ways sensory information can be manipulated.

The Development of Maps

Sensory inputs to brain stem nuclei form orderly arrangements during development, and these nuclei form orderly connections with other nuclei, which in turn project to cortical areas in an orderly fashion and so on. The rough order in at least the early stations of this sequential process seems to depend on intrinsic factors in the brain (Sanes, 1993; Udin and Fawcett, 1988). More specifically, it has long been hypothesized that afferents are chemically labeled according to some gradient, and target neurons are also chemically labeled with a comparable gradient across the target structure. Thus, the neurons find

chemical matches and a topographic map is created. However, chemical or molecular matching is not the only factor in the development of brain maps, since there is much evidence that the development of such maps can be altered by changes in the sensory environment that induce changes in neural activity patterns. The details of sensory maps appear to be fine-tuned by an adjustment and sorting of local connections in largely adaptive ways in response to variations in patterns of sensory activation. The claim is that neurons that fire together wire together. Coactive neurons with overlapping connections maintain and strengthen their synapses on shared target neurons, while neurons that do not respond at the same time tend to weaken and lose synapses on their shared target neurons. Thus, neurons with uncorrelated activity patterns tend to segregate their terminations so as to activate separate groups of neurons in the next structure. This allows maps to adjust and compensate for losses or additions of inputs, and maps in a sequence to adjust to each other (Kaas and Catania, 2002).

There are many types of evidence that maps adjust to sensory changes during development. Usually, this evidence comes from some sort of experiment where some sensory input is removed or altered. Normal inputs expand to activate neurons formerly devoted to the removed or weakened inputs. Other evidence comes from the variations observed in maps in nature. Rats and mice have morphological maps of the whiskers of the face in S1. Each whisker activates neurons in a small oval of cortical tissue that resembles a barrel, and is commonly called a cortical barrel (a barrel-shaped module or column in somatosensory cortex of rats and mice that is anatomically distinct and responds to a specific whisker on the face. The 'barrel field' has a barrel for each whisker of the whisker pad of the face). Rats and mice usually have the same number of whiskers, and there is one barrel in S1 for each whisker. Likewise, there is one barrel-like structure for each whisker for the termination of afferents from the face in the brain stem, and in the ventroposterior nucleus of the thalamus. Thus, maps at three levels of the somatosensory system precisely match the arrangement and number of whiskers on the side of the face. This match could be due to innate developmental mechanisms, such as the matching of connections between levels as a result of a chemical code, but this appears to be unlikely.

Mice have been found that differ in the number of whiskers by having one or two more or less than the normal number, and in these mice the maps at all three levels match exactly the increase or decrease in whiskers. Thus, somehow the receptors in the skin are informing the central maps about their organizational state. In a similar way, the star-nosed mole has 11 sensory rays or protrusions from each side of its nose (Kaas and Catania, 2002). Processed sections of somatosensory cortex reveal 11 corresponding bands of tissue in primary somatosensory cortex, S1, one for each ray. Eleven bands are also seen in the second somatosensory area, S2, the ventroposterior nucleus, and the somatosensory brain stem. Moles with 10 or 12 rays have been found, and 10 or 12 bands are then seen in all four brain structures in these moles. This matching of maps from one level to the next and with the peripheral receptor sheet would be most easily accomplished by a system that uses natural activity patterns to fine-tune its maps.

Why Have Topographic Maps?

Much of the brain is devoted to topographic maps suggesting that they are a useful way of organizing brain tissue. One cannot argue that such maps are simply preserving the order of afferents from the periphery, since afferents become mixed and disorderly, but sort themselves out again as they terminate. Instead, topographic maps appear to be adaptive in that they provide a substrate for making the most common types of computations in the nervous system over short, local connections (Kaas, 1997; Chklovskii and Koulakov, 2004). Neurons in topographic representations are well arranged to make center-surround comparisons between stimuli anywhere on the receptive field sheet, and stimuli in the immediate surround. This type of comparison provides biologically useful information. Neurons rapidly determine if a stimulus at some location is brighter, greener, harder, louder, or moving differently than stimuli in the immediate surround. While it may be possible to make such computations in nontopographic structures and systems, neurons would need to be massively interconnected and over larger distances. This would add unreasonable bulk to the brain, and would be metabolically costly. In complex brains with large amounts of neocortex, it is probably more efficient to have multiple interconnected maps, rather than just making maps larger. Large maps are most suitable for extremely local comparisons of stimuli, while more global comparisons can be mediated over short connections in small maps. Thus, it seems to be more productive to subdivide tasks, and process information in parallel over sequences of interrelated small maps, and use long connections to coordinate the activities of maps within and across processing sequences. Maps vary in size in the same individual because large maps are better at fine-grain local comparisons while small maps are better at more global comparisons.

Abstract

Lawsuits in tort allow victims of other people's wrongful and sometimes merely harmful behavior to claim monetary damages for their injuries. Defenders of tort law extol it as a vehicle for achieving justice, promoting safety, internalizing accident costs, compensating victims, and more. Critics doubt tort law's effectiveness on all these criteria and would prefer legal jurisdictions to follow the lead of New Zealand, which has replaced tort law for personal injuries with a comprehensive accident compensation scheme.

A *tort* is a 'civil' or personal wrong to a private individual or enterprise, and the legal remedy for a tort victim lies in the injured party bringing a private lawsuit against the injurer.

This is in contrast to a 'crime,' which is wrong against society and which can lead to the prosecution of the wrongdoing criminal by public authorities. The conventional social remedy against those who commit crimes is incarceration and/or a financial punishment (a fine) that is paid to the government. By contrast, when tort victims make successful claims against their injurers they usually recover money damages from their injurer (or the injurer's insurer).

Torts are like crimes in the sense that liability is often based upon the violation of standards of conduct set by the society. Yet not all torts are crimes, and violations of many criminal statutes do not injure private actors in ways that would give rise to tort claims.

Tort claims should be distinguished from claims based on breach of promises, claims arising from contract law. Speaking generally, in the latter the victim seeks to hold the injurer to the promise that was privately made, rather than to a socially created standard (although contemporary contract law often reads implied promises into contracts in part to satisfy public goals as well as consumer expectations).

The money damages that tort victims seek are understood to fall into two categories (Luntz, 2008). The first concerns what are typically called pecuniary (or perhaps economic) losses. These include things such as lost income and profits both past (from the time of the tort until the time of the trial or settlement) and future (projected out for so long as those losses are expected to occur). The other major sort of pecuniary loss for which victims sue is the recovery of expenses that have already been incurred and are likely in the future to be incurred because of the tort. The best examples of these losses are medical and related expenses.

The second category of damages is typically termed nonpecuniary or noneconomic. These are damages for what tort law in the United States calls pain and suffering, although that label is generally meant to also capture loss of pleasure, loss of amenities of life, loss of dignity, the upset one feels as a result of an impairment or a disfigurement, and the like. Other legal systems frequently label these nonpecuniary awards using different terminology, such as moral damages.

These sorts of nonpecuniary damages are primarily awarded to those who suffer personal physical injuries, and physical harm to the person will be the focus here. Quite obviously, at the time of a trial or settlement of a case, someone who has suffered a grave disability as a result of another's tortious conduct might still be suffering and be expected to suffer until the end of life. Hence in this respect pain and suffering damages, like pecuniary damages, may be awarded for both past and projected future losses.

Nations differ enormously, however, in the actual amount of nonpecuniary losses that are awarded for similar serious injuries (Sugarman, 2006). Within Europe, victims with similarly grave injuries might win 10 times as much in nonpecuniary damages in some nations as compared with others. And some victims in the United States might well be awarded 10 times as much as would be awarded in the most generous European country. Some of these differences undoubtedly are a product of national wealth and the level of average citizen material well-being which influence judgments about appropriate sums to award. But attitudes toward the disabled and existing social services arrangements for dealing with the disabled in general surely also come into play, as probably do national cultural attitudes toward money in general – because tort law can hardly put victims back into their former state of health but can only offer money as a kind of solace.

Other sorts of indignities – such as invasions of privacy, defamation, false imprisonment, and so on – where recognized as giving rise to tort claims, can also result in the award of nonpecuniary damages, although those sorts of claims will be put aside here. Moreover, although tort claims frequently arise on behalf of those seeking compensation for financial losses, damage to real or tangible personal property, injuries to reputation, and so on, as noted already the focus here will be on personal injury and death. This focus is in accord with US practice; most American lawyers who bring tort claims are typically called 'personal injury lawyers' because bodily injury claims form the core of their legal practice. Things are quite different in New Zealand, however, where tort claims for personal injury have been almost entirely eliminated and replaced by a government-created compensation scheme to deal with all accident victims (Palmer, 1979). There, tort lawyers tend to focus on financial and property injuries.

Concentrating on personal injuries, tort claims arise from a wide range of human interactions. The most important categories of accidents that can lead to tort claims include (1) transportation injuries (accidents involving occupants of autos, planes, trains, buses, and motorbikes, as well as pedestrians who are struck by such vehicles); (2) medical injuries (arising from the failed treatment by physicians and other health professionals, often termed 'malpractice'); (3) product injuries (when a specific item is defective or when an entire line of products is defective with respect to its design or the adequacy of its warnings); (4) injuries that occur on the property of others (such as slips and falls, dangerous conditions that result in accidents, and dangerous activities that lead to harm), (5) recreational injuries (suffered by participants in organized or disorganized sporting and related activities); and (6) work injuries.

Most industrialized nations have separate work-injury compensation schemes (sometimes called workers' compensation or industrial accident schemes) that pay money to those injured in the course of their employment. Nations often allow those suffering work injuries to sue in tort to recover losses not already covered by the industrial accident scheme (although the amount of compensable additional damages is often sufficiently minor that few victims elect to pursue their rights and sue their employers). But elsewhere, such as in all of the US states, for ordinary work injuries the victim's exclusive remedy is though the workers' compensation system; in return for funding this benefit employers are exempt from tort claims (Kramer and Briffault, 1991).

There are pragmatic reasons for focusing a discussion of tort law on personal injury and death cases. These injuries can give rise to devastating harms and very large losses (and sometimes to very large financial recoveries). Personal injury claims for *accidental* injuries tend to be the most numerous sorts of tort claims because all too often those who commit *intentional* torts (which are also frequently crimes, such as murder, rape, and armed robbery) have no financial means to draw on to provide financial compensation to their victims. That is to say, even if they are captured, they are typically judgment proof. Hence society tends to deal with these sorts of wrongdoers through the criminal justice system.

One reason that criminals are frequently judgment proof is that, even if they were to have liability insurance to stand behind them if they were to commit a tort, that sort of insurance does not cover intentional harms (Abraham, 1986). Rather, it only applies to accidental harm, even if tortuously imposed. Hence, you can buy insurance that would pay what you owe in tort if you carelessly drive your auto into someone or carelessly allow someone to slip and fall on your property, but you cannot buy insurance that would cover your tort liability if you wrongfully punch someone in the face. However, sometimes a person or enterprise is sued in tort for carelessly failing to prevent the victim from being injured by someone else acting in a criminal way – for example, a psychiatrist who fails to warn a victim that the therapist's patient is coming to kill her, or a vehicle owner who gives his car keys to a drunk, or an apartment building owner who is aware of criminal attacks on tenants and fails to take reasonable precautions that would have prevented an attack (Franklin et al., 2011). Liability insurance will cover the legal obligation of the noncriminal defendant in these sorts of cases.

It is also true for many countries that the most intellectually interesting and controversial tort cases arise out of accident settings and have resulted in the sorts of judicial rulings that have gained the most sustained scholarly attention (Rabin and Sugarman, 2003).

The tort law of Great Britain, the United States, and many other former English colonies (like Canada and Australia) is said to be 'common law' (Baudouin and Linden, 2010; Dobbs, 2000; Fleming, 2011) and to be distinguished from the tort law of other places, like France, Germany, Japan, and China, where tort law is said to be 'civil law' or 'code law' (Markesinis and Unberath, 2002). Although there are important theoretical and practical differences between the two approaches, not too much should be made of the difference.

Common law is law that is announced by judges in the course of giving their opinions in individual cases that come before them for resolution. In these opinions, judges explain not only what the law is but also state what they believe are the relevant facts in the matter before them and give the reasons why they reached the conclusion they did. This practice helps assure that the judges are at least formally providing reasoned elaborations in justification of their conclusions (although some believe that judges first decide how they feel the case should come out and then construct arguments designed to support that feeling). It also provides analysis for lawyers on both sides of new conflicts to argue about and draw on in trying to predict how judges are going to decide new disputes involving arguably importantly different facts. And these past written opinions provide a trail with which judges must contend when deciding new matters, either following along in what they see as the relevant track or distinguishing or overruling past opinions.

Although it was once imagined that judges would find the law of torts through logic, somewhat analogously to the way that scientists find the laws of physics, this is not a realistic way of looking at things. To be sure, common law judges tend to give great deference to the decisions of other judges in prior similar cases, following the principle captured in the Latin phrase *stare decisis* (the doctrine of precedent). Yet this too should not be overemphasized. First, the obligation to follow precedent is said to apply only to 'lower' or 'inferior' courts with respect to prior decisions of higher courts. Second, in torts cases especially, the facts are always different if one digs deeply enough, and judges quickly became expert in distinguishing prior decisions they do not like by emphasizing different facts in the matters before them. Third, the top-level courts in all common law jurisdictions reserve the right to change the law if they see fit, and they do so. Many reasons are employed to justify such changes, including the argument that social circumstances and/or expectations have changed, contemporary morals are different, new situations have developed to which it makes little sense to apply old principles adopted for other times, the prior decision was (alas) never persuasively reached in the first place, and so on.

Hence, on the ground, so long as the relevant legislative bodies keep out of the way, the common law of tort in each country is perhaps best seen as an organic system that evolves under the direction of judges in furtherance of the values and

other factors they believe best suit the contemporary world. And if the judges are seen to have gotten it wrong, then the relevant legislature can and sometimes does intervene and overrules what the judges have decided. So, for example, when the California Supreme Court decided, as a common law matter, that a social host has a legal duty of care to take reasonable steps to assure that his or her social guest who has drunk too much alcohol at the host's home does not leave and, as a drunk driver, carelessly run someone else down, the California legislature decided that this was inappropriate and by statute changed the law (Franklin et al., 2011).

In the United States, this debate usually occurs at the state level, because in the United States tort law is state law. In fact there is no national body of tort law in the United States, but rather 50 different bodies of tort law in the 50 different states (and although on most issues the laws of all the states are similar, on many controversial matters they are not).

In Canada and Australia, unlike the United States, there is a national common law declared by the highest court of each nation. But there too, like the United States, provincial and state legislatures may and do sometimes act to change by statute the tort law in their jurisdiction. For example, not long ago in New South Wales, Australia, the government restricted the amount of a victim's lost income that tort law would replace to three times the average wage in the state (Fleming, 2011). In England and Wales, it is normally the national Parliament that would change the common law as it did decades ago, for example, when adopting the principle that the victim's contributory negligence would no longer be a complete defense but rather would serve only to reduce appropriately the damages a victim could receive from his or her careless injurer (Arvind and Steele, 2012).

In civil law nations, it is said that judges simply apply the law as laid down by the government, which in many places (unlike the United States) is, in effect, a combination of the executive and legislative branches, because in parliamentary democracies (or even in monarchies or tyrannies) the political leadership commonly simultaneously controls both the legislative and executive functions. Yet it is not our worldwide experience that governments in civil law nations are routinely altering their law of torts in substantial ways. To the contrary, they generally tend to have adopted a few basic statutory legal principles that form the core of their civil code. In many places these codes may be ultimately traced back to the Napoleonic Code or even earlier, say, to Roman law. To be sure, just as there are statutory changes made in the common law of torts, so too civil code countries update, alter, and make more complex their respective bodies of tort law. But in the end many of the key decisions of courts in civil law nations reflect the efforts of judges, as best they can, to apply long-established simple principles of justice to new and changing events. In this respect, they are, as a practical matter, often functioning very much like common law judges. The tradition of writing opinions in civil code jurisdictions varies, however, so that it is not infrequently the role of academics to try to rationalize new decisional outcomes with the pattern of past interpretations of code provisions.

Interestingly enough, until lately noncommon law nations avoided use of the word 'tort,' with countries like France being traditionally said to have a private or civil law that covered both what the English would term tort law and contract law. This is now changing, and many now speak of European tort law, German tort law, and French tort law, which is perhaps a welcome relief because the word 'tort' itself has a French origin. When the common law of torts was first evolving, the elites of England, at least in the legal world, wrote in what is sometimes termed 'law French,' since the evolving English language was left more to the common man (not the common law).

The curious thing here is that even today the word 'tort' in contemporary French is ambiguous in its meaning and brings us to a fundamental issue in the law of accidents. Many would say that 'tort' means 'wrong,' but others would say that it also, or perhaps even better, means 'harm.' This distinction is critical. If tort law is about wrongs, then it rests on the principle that you may shift your losses from yourself to another through tort law when that other has wronged you – that is, when the one you sue has misbehaved in a way that resulted in your injury. If all that is required is harm, however, then one who innocently injures you may also be held legally responsible for the consequences of his or her behavior.

In contemporary parlance, this raises the question of whether tort law does or should rest on the 'fault' principle or whether people should be 'strictly liable' (that is, liability in the absence of fault) for harms they cause (Calabresi, 1970). Of course, many defendants act in a faulty way and hence would be liable in tort whether the system rests on the fault principle or on a strict liability principle. The difficulty comes when you or your activities generate injuries for which one would say you are not to blame in this specific sense: the victim is not saying that you should have acted differently, in a manner that would have avoided the injury; rather, the victim is saying that it was not socially objectionable for you to have acted as you did, but nonetheless you should compensate me for my loss that your behavior caused.

As will be discussed later in the article, there are good reasons that can be put forward in support of a system of strict liability – at the least in situations in which the injurers are enterprises and the victims are ordinary people. But in fact, at least on the books, the law of torts around the world is primarily a fault-based system. The victim must show that he or she was wronged, that he or she should not have been injured, and that the defendant in the lawsuit acted, as they say in the United States, 'unreasonably.' More precisely this means that the defendant failed to act in the way that a prudent person would have acted, taking into account the riskiness of the defendant's act and the burden that would have been born by the defendant to have avoided the harm.

In many legal systems, there are islands of strict liability in this sea of fault liability (Dobbs, 2000; Fleming, 2011). Some places, for example, have effectively made the law governing auto accidents one of strict liability (although in many places the law governing auto accidents is not really tort law anymore, but rather a separate statutory scheme for compensating victims of auto accidents on a no-fault basis). In many places, when a manufacturer provides a product that is defective in the sense that something is wrong with it (it is dangerous in ways that the product maker did not intend and the victim did not expect), there is strict liability in the sense that it is no excuse that the manufacturer employed the best

available inspection system and no such system could have detected the defective item before it caused injury; proof of lack of due care, in short, is not required. And in some places like the United States, if the actor is carrying on certain abnormally dangerous activities, like dynamite blasting, then he or she is liable for harm done even if the activity was carried out in an altogether reasonable manner and simply unavoidably went astray. Although there are other examples, the instances in which liability is 'strict' are but a few of the many ways in which people are accidentally injured, and for those many ways proof of fault is typically required.

In trying to untangle this fault versus harm conundrum, we should attend to the functions of tort law and appraise how well tort law in fact achieves the goals that many have set for it.

For some, tort law has an almost magical character (Geistfeld, 2008; Portat and Stein, 2001). Its threat, they believe, prompts most people and businesses to act properly. Hence, we achieve socially desirable levels of safety (accident prevention) without the cost and heavy hand of bureaucratic regulations. People who violate community standards and injure others are held accountable through a privately initiated system that delivers victim compensation and yet involves only minor public costs of administration. Holding wrongdoers accountable in this way achieves corrective justice in the sense that victims are 'made whole' to the extent that money can do that, and injurers are punished for their sins. Moreover, the costs of injuries that should have been avoided are now internalized into the cost of the activities that caused the harm (and are thus either reflected in the price of those activities or in reduced profits for shareholders). Because the government makes available this form of redress, people who are wronged (and their families) are less likely to seek vengeance against wrongdoers through private violence.

Notice how the social goals that tort law is said to serve by these lines of argument might be separated into social welfare (or utilitarian) goals and fairness (or moral) goals – perhaps counting compensation of victims, cost internalization, pre-empting violent revenge, and accident reduction as utilitarian and then counting justly putting victims back in the position they were in before the injury, as well as punishing wrongdoers and giving satisfaction to victims on the fairness side. Note also that this package of social goals said to be served by tort law rests on the assumption that tort law is fault based.

Others, sometimes termed 'legal realists,' are rather doubtful about the actual achievements of tort law in action with respect to these goals (Sugarman, 1989). They may scoff, for example, at the actual deterrence impact of tort law on unsafe conduct. After all, private morality, market pressures, self-protection instincts, and existing governmental regulation already promote safer conduct. For that reason, it is not clear just how much more tort can achieve, especially once it is appreciated that many individuals from time to time are just not up to behaving with appropriate caution, that executives can only have so much success in training staff to take due care when those employees simultaneously are being pressed to maximize firm profits, and especially when the costs of precaution are born now and the costs of failing to do so might not be incurred until later, when the existing executive leadership is long gone. Furthermore, as a practical matter, both individuals and firms that carelessly cause injuries are generally insured against their tort liability, so the actual monetary price they pay is only secondarily reflected, if at all, in higher insurance premiums after the fact.

Empirical studies of tort law's role in promoting greater safety (Dewees et al., 1996) are mixed, although some have found tort to have a positive, if perhaps modest, impact in the right direction. Others researchers have found that tort law can have negative impacts in terms of overdeterrence (for example, excessive investment in safety through doctors wasting health resources on too many medical tests) or the withdrawal from the society of socially desirable activities (such as removing equipment for children to climb from school playgrounds).

Skeptics also question the sensibility of viewing tort as a way to appropriately compensate victims. First, the administrative costs of the system are enormous as compared with typical private insurance or public social insurance schemes. In the United States, for example, costs of administration (especially legal fees on both sides) account for about half of the cost of the system, so that benefits to victims are only about half of what is spent. Besides that, a significant share of the benefits that are provided by tort law duplicate benefits already provided by other sources such as health insurance and Social Security, leading either to double recovery or yet more administrative expense as the double payment sum is recouped by the collateral source. Second, as compared with social insurance that generally limits the lost wages it replaces, tort law is very generous to the rich, providing full compensation for lost income (in most jurisdictions) that makes the system rather 'regressive' in its impact (and explains why New South Wales, as noted earlier, decided to cap the level of income replacement). Third, not all accident victims are compensated via tort law. This is both because some injurers are financially unable to pay what they owe and because some victims are injured through no one's fault or perhaps theirs alone (and when both parties are at fault, then in most systems compensation is reduced or perhaps even eliminated). The existence of liability insurance also blunts the punishment function of tort law, and even more so when victims are injured by employees of enterprises, because it is the firm that pays – not the actual worker who committed the tort.

Although tort liability does internalize some accident costs into activities that cause them, it does not fully do so unless strict liability is employed, but that is rarely the case at present. A much more sweeping embrace of 'enterprise' liability (strict liability for business defendants, especially in claims brought by individuals) would more fully internalize accident costs into the relevant enterprise activity. It would as well provide compensation to many more victims. Yet on the other hand, if tort law were to become mostly a matter of strict liability, then its current functions of identifying wrongdoers and punishing them would be undermined. This reality shows the deep tension that exists when trying to use tort law to simultaneously serve multiple functions.

Turning to yet more tort law goals, one can also be skeptical about how well tort law actually satisfies victims' sense of justice. In practice many tort victims do not sue. Some are unable to find a solvent defendant who would be liable for their injury. Others are unable to prove that they were victims of someone's fault even though that was the case, and in some

situations that is because injurers have hidden or even destroyed incriminating evidence. A number of victims – for example, in medical injury cases – do not even realize they were victims of negligence. And some who have theoretically valid claims cannot find lawyers to represent them because the costs of litigation will outweigh the small amount of damages they could recover (a problem especially severe in medical injury cases in the United States, where each side bears its own legal fees). When victims do sue, their cases normally settle without trial, and settlement agreements typically include a 'no liability' disclaimer. This can be highly frustrating for victims who want to formally hold their injurer accountable. Worse, many find the litigation and settlement process highly unpleasant. Their own lawyer often ignores them, the other side subjects them to harsh treatment, cases seem to go on endlessly for no discernible reason, and so on. These realities often undermine the idea that tort law brings moral satisfaction to victims.

Finally, today's organized and reasonably effective police forces, social norms, and fears of criminal prosecution are likely to be more effective than the promise of tort recovery in discouraging violent vengeance especially against those who have merely accidentally, even if negligently, committed torts.

Tort law is far more robust in the twenty-first century than it was in the past (Sugarman, 2000). Take lawsuits against physicians, for example. Although these have long been theoretically available to patients who have been injured by medical malpractice, in the past the idea of suing one's family doctor was sharply counter to social norms, especially when the doctor often provided helpful service over the years. Moreover, it was traditionally very difficult to find a doctor who would testify against another doctor, and yet winning a malpractice case almost always requires relying on an expert witness. Nowadays, at least in some places, medicine is seen as more of a business, medical specialization means that a doctor who injures you may well be someone you have never encountered before, the public is far more aware that doctors sometimes make careless mistakes that lead to catastrophic consequences, and getting a third-party doctor to stand up for the victim is no longer quite so difficult (certainly in US jurisdictions that now permit testimony from any qualified expert instead of requiring a local expert).

So, too, product liability litigation is far more promising for victims than in the past. At one time manufacturers of defective products could only be sued by their direct buyers, a rule that effectively immunized them from liability once sales of products began to be carried out through retailers. Later, manufacturers could be sued when their negligence caused a product defect that injured someone. Nowadays in many nations, product makers are strictly liable for defective products they produce, and a subset of expert lawyers specializes in these sorts of cases, leveling the playing field in litigation against large-scale enterprises.

One aspect of tort law that remains peculiarly American is the widespread use of lay juries to decide liability in most tort cases (Fleming, 1988). Elsewhere juries are either never or rarely used in civil cases. Although there is a strong ideological commitment to juries in America, it is probably fair to say that their use introduces uncertainty and variability into legal disputes over accidents. In turn, although 'tort reform' is a mantra of certain defense interests in other nations as well, it is in the United States that business interests and some conservative political players have most actively sought to 'rein in' tort law. Because conservatives are committed to the idea of personal responsibility and certainly are not eager to replace tort with more government regulation of safety, it is perhaps not surprising that most 'tort reform' has been in the form of either reducing the amount of money that tort law may award victims or changing tort procedures, rather than moving away from fault liability. These changes, where enacted (and in the United States this mostly means on a state-by-state basis), have somewhat lowered the stakes of tort litigation. Still, personal injury law remains a frequently wielded tool in the United States whenever plausible connections between solvent injurers and victims can be made (Shapo, 2012).

Indeed, many today defend tort law precisely as a mechanism for uncovering and then disclosing misconduct by those in charge of large institutions that all too often seems overlooked by government officials. In short, the 'ombudsman' or 'private attorney general' function of personal injury lawyers is one of their strongest claims for promoting the public interest (Linden, 2003; Lytton, 2008).

Abstract

Torture is utilized around the world to intimidate and punish individuals. The psychological damage created by torture has far-reaching effects on both the victim and the perpetrator. The extreme trauma leads to numerous mental health and behavioral complications, such as post-traumatic stress disorder, complex post-traumatic stress disorder, depression, anxiety, and addiction. Some individuals even report being fascinated by the violence, exhibiting appetitively aggressive behavior. narrative exposure therapy, and narrative exposure therapy for forensic offender rehabilitation are two mental health interventions designed to treat both torture victims and perpetrators, respectively, and assist in the reintegration process into society.

Introduction: Definition and Direction

Internationally, the currently utilized, institutional definition of torture provided by the United Nations Convention Against Torture delineates a top-down politicized act in which one person, under the acquiescence of governing authorities, intentionally inflicts severe pain or suffering on another with the objective of obtaining information, inflicting punishment or discriminating via intimidation. The definition concludes by emphasizing in Article 1, Section 1 that torture "does not include pain or suffering arising only from, inherent in or incidental to lawful sanctions" (United Nations, 1984). Specifically, demarcating torture as an event that occurs only outside of 'lawful sanctions' perilously politicizes the human experience of torture as an issue isolated to distant lands and cultures beyond the scope of Western legal standards. And when it does occur in the West, for instance, in prisons such as Guantanamo Bay, the torture practices utilized are neatly renamed interrogation techniques, and laws are shifted to redefine such practices within the requirements of legal sanction. In juxtaposition to popular thought, torture is far from being isolated to remote crisis regions or Western prisons detaining the terrorists stemming from those crisis regions. Torture is reported in numerous countries around the world (Amnesty International, 2013) and effectively establishes a feeling of fear, horror, and intimidation in the population at large.

Conceived in 1984, this outdated, sterilized definition is structured politically and omits the wide array of experiences and individual motivations of both the victim and the torturer. Unfortunately, torture is an event that is neither so simple nor so distant. From an educated, highly trained top-level government interrogator to an orphaned, hungry, child soldier in a rebel group to a gang member having caught a member from the rival gang, the varieties in the purpose of torture and how it is administered go as far as the limits of human creativity. Torture is as ubiquitous as people and as complex as the labyrinth of physiological and psychological mechanisms that constitute the human experience. A more comprehensive understanding of torture involves investigating both the neurological and the mental health underpinnings at the individual level of both the victim and perpetrator.

The Torture Victim: Experience and Consequences

A victim of torture can be forced to endure a wide array of terrifyingly painful physical and mental suffering. From extreme isolation, sleep deprivation, and highly uncomfortable sitting and standing positions to starvation, waterboarding, electric shock, limb removal, and fake executions, the victim never knows when the current treatment will end or what to expect next. Unable to escape, the victim reacts to the threatening stress of torture with a series of functionally distinct psychophysiological responses that operate as a defense cascade. This defense cascade follows the order of freeze-flight-fight-fright-flag-faint (see **Figure 1**; Schauer and Elbert, 2010). Initially freezing, the individual senses a threat, stops moving in an attempt to remain undetected, and increases attention. If the threat increases, the individual moves into flight or fight mode to protect him- or herself. Fight or flight mode increases sympathetic activation, thus enabling physiological reactions, such as tachycardia and peripheral vasoconstriction to minimize bleeding. Fear, but also anger and rage, enable the individual to fight back. The final stages of the defense cascade function to cope with situations in which the threat is overwhelming, fighting is useless, and the organism can only minimize damage. The individual becomes motionless, with motor paralysis, sensory deafferentation, and dissociative psychological conditions that range all the way up to a complete shutdown (Schauer and Elbert, 2010; Bracha, 2004; Bovin et al., 2008; Fusé et al., 2007). In trauma situations involving physical fighting and self-defense, the earlier phases of the defense cascade may be activated, while in situations in which the victim is overpowered, such as with torture or rape, the later phases are activated.

Typically, for nontraumatic memories, the initial sensory, emotional, physiological, and cognitive concomitants of an event, the 'hot memories,' gradually become integrated into declarative or 'cold' memory temporal context, can be recalled consciously and consequently are perceived as memories (Brewin et al., 1996, 2010; Brewin, 2011; Elbert and Schauer, 2002; Schauer et al., 2011). For example, when an adult recalls happily holding a puppy, the individual simultaneously remembers that the puppy was a gift, it was summer time, and family members except for the unborn

Figure 1 Schematic illustration of the defense cascade as it progresses along the 6-F course of action. The "uproar" sympathetic arousal reaches a maximum at the fright stage, eventually superseded by the onset of dissociative "shutdown" (gray area).

younger brother were present, and thereby it occurred at the person's fifth birthday party. Traumatic memories, however, function differently. The *hot memories* of traumatic events are so overwhelming that they do not consolidate with the *cold memory* temporal and spatial context (Brewin et al., 2010; Brewin, 2011). These experiences remain separate from autobiographical memory but still manifest themselves as vivid intrusions and nightmares. They seem to be lurking in the mind, and on the cue of the slightest, perhaps even unrecognizable, reminder of the trauma, they spring to the surface of the survivor's awareness. The sight of an officer's uniform, the sound of extremely loud heavy metal music, or the sensation of being under water at a swimming pool can reactivate the chain of connected associations that compose the hot memory, and the person perceives that he or she is once again in the torture situation. In such situations, although the survivor physically is located in the present, he or she remains mentally and psychologically situated in the past, in a network of experiences that never have been assigned the proper place and time (Brewin, 2011; Schauer et al., 2011).

The most characteristic symptom of trauma disorders is this intense reliving of these experiences as though they currently are happening, rather than being a part of a memory from the past (see Figure 2). When the torture survivor is suddenly in a situation with hot memory cues and the body begins to react as though the traumatic event is occurring in that moment, panic, horror, or dissociative responses set in (Elbert et al., 2011). At the initial stages of the defense cascade, the events are vividly present in all their components: sensory (smell of blood), physiological (heart racing, shortness of breath),

Figure 2 Multiple adversities affect a dynamic, self-organizing system that may continue to change, i.e., driven to a different system attractor with altered processing dynamics.

emotional (terror), and cognitions ('I'm going to die') (Schauer et al., 2011). The cold memory historical context placing the prior traumatic events in the correct time and space is missing, rendering the survivor seemingly defenseless to the physiological reactions to the perceived stress (see Figure 3). Torture survivors may have learned to rather rapidly switch to the later stages of the defense cascade, where dissociation sets in and current sensory information is gated and perceived as distant and unreal. Intrusions

Figure 3 A fear/trauma network results from multiple fearful experiences: the representation of a single event may well connect to the context and episode. If, however, the perception cues an already existing trauma network, the context is lost while sensory, cognitive, emotional, and physiological representations interconnect with increasingly mutual excitatory power. The codes of "where" and "when," however, are not consistently co-activated as the brain's architecture does not support the simultaneous activation of two different places coded in the hippocampus. Thus the fear/trauma network becomes disconnected (symbolized by the scissors) from time and place, and the fear generalizes, giving rise to feelings of impending threat. Narrative Exposure Therapy is thought to reverse this process by contextualizing the trauma network. Adapted from Schauer, M., Elbert, T., 2010. Dissociation following traumatic stress. Zeitschrift für Psychologie/Journal of Psychology 218 (2), 109–127.

therefore can be understood as repetitive displays of parts or fragments of the event, which then elicit a corresponding combination of hyperarousal and dissociation, depending on the dominant physiological responding during the torture situations. Subsequent trauma-related disorders, such as post-traumatic stress disorder (PTSD) and other forms of disorders of extreme stress, represent the chronic reactivation of these defense cascade reactions (Elbert et al., 2011).

PTSD is the most frequently reported consequence of trauma, especially in cases of atrocities perpetrated by human beings (De Jong et al., 2001). PTSD is correlated linearly with traumatic experiences and outlines a type of building block effect for trauma in which each additional traumatic experience is accompanied by an increased likelihood that the individual eventually will develop PTSD (Neuner et al., 2004). It is a condition that occurs when an individual experiences an event that threatened survival or physical integrity. PTSD involves recurrent, disjointed, fragmental memories of the traumatic event, often in the form of flashbacks, that the sufferer strives to avoid, resulting in a hyperaroused, easily irritated, distracted state. It persists over longer periods of time and can be extremely debilitating in many areas of social and occupational functioning (American Psychiatric Association (DSM-V), 2013). The devastating effects of PTSD dramatically affect the transition of many torture survivors to their homes, and the individuals are markedly different upon return than when they left. Because of coverage by the mainstream media, the public acknowledges that many returning soldiers might contend with PTSD. Research is now beginning to acknowledge that soldiers, especially if they were taken as prisoners, might be dealing with trauma symptomology that affects the very sense of self with an altered personality. The changes are related to macroscopically altered brain function in torture survivors (Elbert et al., 2006, 2011; Ray et al., 2006) and structure (Eckart et al., 2011). Lateral prefrontal, parietal, and posterior midline structures have been implicated in the pathophysiology inflicted by torture (Eckart et al., 2011). As these regions are involved specifically in episodic memory, emotional processing, and executive control, this might have important implications for the understanding of the trauma-related symptoms. Long-term effects on the immune system (Sommershof et al., 2009) and overall physical health also have been noted in those individuals exposed to torture-related stress.

Recent work with torture survivors has demonstrated that prolonged adulthood trauma also can result in complex post-traumatic stress disorder (CPTSD) symptoms (McDonnell et al., 2013). CPTSD encompasses all of the symptoms

of PTSD and also incorporates the severe personality disorganization that can occur in some individuals following long periods of threat stress (Kolb, 1989). Conventionally, CPTSD has been associated with childhood trauma, however, researchers have shown that repeated and multiple traumatic events during adulthood lead to the breakdown of self-regulatory abilities – even in the absence of childhood trauma (Cloitre et al., 2009). Moreover, CPTSD symptoms are more closely related to the nature of the traumatic event rather than to the developmental stage of the individual at the time of the event (McDonnell et al., 2013). Perhaps the direct link of why CPTSD can occur in adults without childhood abuse owes to the captive nature of torture. Unable to fight or flee, the dissociative states associated with the latter half of the defense cascade, such as voluntary thought suppression, minimization, and denial, engage. These protective mechanisms can result in dissociation, depersonalization, and even changed identity as associated with CPTSD (Hárdi and Kroó, 2011). These responses, over a prolonged period of time and under various levels of static duress, can manifest in three disorders that are not part of PTSD diagnostic criteria: dissociative identity disorder, borderline personality disorder, and somatization disorder (Herman, 1992). Continued research with survivors of torture demonstrates that we have only begun to recognize the vast array of mental health complications with which torture survivors will have to contend.

Alongside PTSD and CPTSD, numerous comorbid conditions abound. Major Depression, Dysthymia, Phobias, Alcohol and Drug Abuse, and Conduct Disorder are among the most frequently observed disorders comorbid with PTSD (Kessler et al., 1995). Although it is possible for comorbid disorders to occur independently from the traumatic event, the comorbid conditions often are extensions of the PTSD symptomology (Schauer et al., 2011). For example, a torture survivor may just want to avoid thinking about past events by avoiding friends and family and drinking, behaviors possibly leading to a clinical depression or substance abuse diagnosis. Such an individual battling a trauma disorder, depression, and addiction among the various other socioeconomic and political obstacles involved with reintegrating into society would require specific, comprehensive treatment if reintegration to normal life is to be even remotely successful.

The Torture Victim: Narrative Exposure Therapy as a Treatment Option

Numerous treatment modalities are involved in treating trauma disorders, but few interventions are developed specifically to address the diverse complications of the trauma involved in torture. Narrative exposure therapy (NET) is an evidence-based treatment approach designed to treat survivors of organized violence who have endured multiple or continuous traumatic stressors (Schauer et al., 2011) and has proven effectiveness in torture survivors (Hensel-Dittmann et al., 2011; Neuner et al., 2010) (see **Figure 4**). NET addresses both the personal consequences and the political aspects of organized violence and torture. First, to reduce trauma symptoms, NET utilizes exposure therapy. Patients are confronted with their hot memories of traumatic events as means to connect their current emotional responses to the appropriate place in time from which they originate. Second, in an attempt to organize the fragmented, inconsistent autobiographical cold memories, the patient and therapist work together to reconstruct a consistent narrative of the survivor. The end goal is stabilized trauma symptomology, improved overall functioning, and a narrative that provides both an autobiographical structure for the survivor and testimonies that prove instrumental in human rights legislation. Evaluations by outside researchers demonstrate that NET is a promising, evidence-based intervention ideal for war-related trauma disorders (Robjant

Restructuring traumatic memories: **Narrative Exposure Therapy (NET)**

Based on the model presented in Figure 3, Schauer, Neuner and Elbert have developed the psychotherapy NET (2nd edition of the manual, Schauer, Neuner & Elbert, 2011).

In NET, the patient, with the assistance of the therapist, constructs a chronological narrative of her/his life story with a focus on the traumatic experiences. Fragmented reports of the traumatic experiences will be transformed into a coherent narrative. Empathic understanding, active listening, congruency and unconditional positive regard are key components of the therapist's behavior. For traumatic stress experiences, the therapist asks in detail for emotions, cognitions, sensory information and physiological responses and probes for respective observations. The patient is encouraged to relive these experiences while narrating without losing the connection to the "here and now." Using permanent reminders that the feelings and physiological responses result from memories, the therapist links these memories to episodic facts, i.e. time and place. The imagined exposure to the traumatic memories is not terminated until the related fear presented by the patient demonstrably reduces. In this way, the therapist is supportive yet directive in the elicitation of the narrative in order to counter avoidance and recover the full, implicit information of the trauma. As the end of treatment, the recorded autobiography may be used for human rights advocacy.

NET has several advantages compared to other treatment approaches. Although the duration of treatment is short (varies between 4 and 12 sessions have been tested), the method of narrating the entire life story does not require the patient to select a single traumatic event from their trauma history. Additionally, the fact that the survivor receives a written biography as a result of the treatment has turned out to be a major incentive especially for victims of human rights violations to complete treatment.

Figure 4 The therapeutic agents of NET: (1) active chronological reconstruction of all important events of the autobiographic/episodic memory - 'life line approach'; (2) prolonged exposure to the 'hot spots' and full activation of the fear memory in order to modify the emotional network; (3) meaningful linkage and integration of psycho-physiological and somato-sensory responses to the time-, space-, and life-context; (4) the cognitive reevaluation of behavior and patterns, as well as reinterpretation of the meaning-content through reprocessing of negative, fearful, and traumatic events; (5) regaining of survivor's dignity and satisfaction of the need for acknowledgment. Explicit human rights orientation of 'testifying.' Schauer, M., Neuner, F., Elbert, T., 2011. Narrative Exposure Therapy, second ed. Hogrefe & Huber, Göttingen.

and Fazel, 2010; Crumlish and O'Rourke, 2010; McPherson, 2012). Moreover, NET is a low-cost, relatively short-term intervention and is designed to be taught to local counselors, making its implementation feasible in most settings, regardless of infrastructure and access to resources (Jacob et al., in press).

After considering the mental health implications and suitable treatment options for the victim of torture, the journey to alleviate the consequences of and even to prevent torture is far from over. To prevent torture, we need to better understand not only the systems behind it but also the individuals perpetrating torture (i.e., their motivations, mental health, and rehabilitation options). Most research on torture largely focuses on understanding and treating the victim, all the while neglecting the mental health needs and rehabilitation of the perpetrator. Unfortunately, there is very little quantitative research on torturers themselves. Because all torturers are humans with brains and minds, and many are combatants with the specific task of torturing captives, combatant research, and general neurological studies are the primary available data sources from which to draw.

Figure 5 Major brain regions associated with PTSD: (1) prefrontal cortex; (2) including the anterior cingulated cortex; (3) hippocampus; (4) amygdala (from Kolassa, I., Elbert, T., 2007. Structural and functional neuroplasticity in relation to traumatic stress. Current Directions in Psychological Science 16 (6), 321–325).

The Torturer: Motivation

What motivates an individual to participate in torture? Perhaps some of the most informative clues about what motivates individuals lie in the overarching systems of torture training and implementation. One source of such training is in military organizations. Governments and militaries bear the burden of maintaining some semblance of transparency and accountability for their actions – for example, when a regime is accused of crimes against humanity, such as torture, they are required to provide a defense or explanation for such actions. One of the most prevailing rationales motivating the perpetration of torture is based on the belief system that torture yields accurate intelligence.

As mentioned, the United Nations publically lists the obtaining of information or confessions as a goal of torture. However, the objective of gathering intelligence using advanced interrogation techniques, that is, torture, raises red flags due to its stark inconsistency with current neurological research on memory function. O'Mara (2011) asserts that there is a popular belief that extreme stress or torture is an effective way to elicit intentionally withheld information and memories. There is little to no public research on the accuracy of the information that results from torture. If anything, interrogation techniques that involve extreme, consistent, and prolonged stress will achieve compromises in both the memory function and executive function (O'Mara, 2009). In other words, not only is the factual content of the desired intelligence contaminated but also the intention to withhold information is confounded. If stress is to be understood as the foreboding perception that present or future events will be very unpleasant and uncontrollable, and this perception results in heightened excitability in the brain and body (Kim and Diamond, 2002), torture can be categorized as an ultimate form of stress – both in intensity (consistent and overwhelming life threat) and duration (often 6 months or longer (O'Mara, 2011)).

The ultimate form of stress involved in torture has a significant neurological impact. The hippocampus and prefrontal cortex are the signature regions of the brain essential for normal memory function, and when they function improperly, as when under extreme stress, memory can be impaired (see **Figure 5**). When the stress condition persists over a prolonged period of time, normal physiological functioning of the brain regions governing memory is disrupted and can lead to tissue loss (Arnsten, 2009; O'Mara, 2011; Ulrich-Lai and Herman, 2009). For example, the prefrontal cortex becomes hyporesponsive, showing signs of tissue loss, while the hippocampus loses volume and slows in neurogenesis (Roozendaal et al., 2009). These reductive changes in brain structure and function result in conditions less than ideal for an interrogation. Furthermore, a common consequence of frontal lobe disorders like the ones listed earlier is confabulation, the pathological production of false memories (Turner et al., 2007). Confabulation likely would be one of the least desired effects for advanced interrogation sessions as the torturer tries to navigate around intentional misinformation (lies) and unintentional mistruths (confabulation) to uncover the intentionally withheld truths.

In summary, the notion that torture productively elicits accurate information unravels in the face of research on the neurological anomalies that result from prolonged stress. These anomalies evince that prolonged stress would counterproductively yield an indiscernible mix of accurate and inaccurate information. As there is no evidence that torture elicits significant amounts of accurate information and that the extreme stress involved in torture actually could produce false memories and misinformation, torture must persist for reasons other than collecting intelligence.

Perhaps the motivation behind the practice of torture is simple: power and control. The obtainment and maintenance of power and control more clearly pertain to the overarching authorities typically seeking to induce horror and intimidation in certain populations like ethnic or religious minorities. At the individual level, the mechanisms behind the transformation of a seemingly average civilian into a torturer can extend beyond exerting power and control over others so far as to develop a fascination in violent or aggressive behavior.

The Trained Torturer: Experience and Consequences

During a conflict, one group wants to dominate the enemy group, and torture is a clear way to demonstrate power and exert control by instilling fear. The torturer, however, is not a generic embodiment of groupthink. The torturer is a human being, very likely composed of all the same emotions and desires for fulfillment and survival as anyone else. In the same way that the victim adapts to the conditioning involved with torture, most torturers (excluding those who might be considered psychopaths and are not acting as part of a group) are similarly conditioned (Elbert et al., 2010). The individuals who torture others during conflicts most often are not renegade soldiers fulfilling their own malicious desires. The torture they commit is part of the broader goal of the group they represent, that is, a goal to dominate and intimidate. These individuals are carefully selected and trained. They often are given specific orders of what to do and how to do it. They are punished if they do not follow orders. They are cut off from their families and communities, made dependent on their superiors, and given promises of reward and honor. Some combatants who engaged in torture reported being physically abused by their commanders and witnessed public displays of horrifying acts of brutality and cruelty. Others were abused as children and adolescents. The terror of these experiences evolved into submission and desensitization, and cruelty became a passing, trivial act. The elaborate training process of torturers involves deliberately desensitizing the individuals to violence, diminishing the revulsion associated with gruesome acts through violent chants and songs to build camaraderie, and dehumanizing the target through group-specific language to make it easier to maim and kill the enemy (Gibson and Haritos-Fatouros, 1986). These combatants often are not in a position to easily escape their commitments to the group without fear of a fatal reprisal. One of the most terrifying reported development of some combatants is the gradual shift from violence as not only normal and acceptable but also exciting and a signal of skill (Maclure and Denov, 2006). They are swept up in a cycle of violence in which they have no alternative other than to continue participating in even more atrocities. Trapped, they have to choose between death and a brutal existence in which they will undoubtedly experience a change of their own personality.

The torturer is a combatant, sometimes with the same general warfare tasks as other soldiers and sometimes with the unique role of torturing captives. Sometimes torture is part of the role for all combatants in a group. For example, combatants from Sierra Leone reported fighting at the frontline, looting, burning villages, and the deliberate killing, maiming, and torturing of civilians (Maclure and Denov, 2006). In the chaos of armed conflict, combatants are often simultaneously both perpetrators and victims of violence (Betancourt et al., 2010; Maclure and Denov, 2006; Medeiros, 2007; Schauer and Elbert, 2010) and, as a result, can be left to contend with various mental health complications. Substance abuse commonly is documented among torturers (Rayfield, 2007). Additionally, perpetrators are vulnerable to developing PTSD, whether it be due to the traumatic experiences of being a victim (Annan et al., 2009; Elbert et al., 2006) or possibly stemming from the act of killing (MacNair, 2002). In addition to substance abuse and the broad spectrum of complications related to PTSD, combatants also are confronted with new attitudes about violence that could lead to aggressive antisocial behavior (Elbert et al., 2006; Weierstall and Elbert, 2011).

Figure 6 Facilitative aggression (reactive) usually associated with anger, encompasses any form of behavior that is directed to fighting another person and intends harm in order to reduce threat and fear, thus reducing the aversive arousing state. Appetitive aggression (predatory) also aims at harming others, however, the goal is to achieve a rewarding state which can result from the gains, but also simply from a 'desire' to hunt (from Weierstall, R., Elbert, T., 2011. The appetitive aggression scale. European Journal of Psychotraumatology 2, 8430. http://dx.doi.org/10.3402/ejpt.v2i0.8430).

As mentioned, former combatants report not only acclimating to perpetrating violence but also beginning to perceive violence as fascinating and appealing (Elbert et al., 2010; Maclure and Denov, 2006). They develop the fascination of a hunter – a human hunter (see **Figure 6**). This fascination to violence and aggressive behavior without the benefit of any immediate reward, appetitive aggression, is related to higher rates of perpetrated violence and demonstrates functioning as a buffer against PTSD under certain conditions (Elbert et al., 2010; Hecker et al., 2012; Weierstall et al., 2011, 2012). Although they initially might have been motivated to torture others to fulfill their duties or to preserve their own lives, some torturers have now grown to relish the violence and crave to repeat it for purely hedonistic purposes.

The combination of the instability of substance abuse and trauma symptomatology with the relishing of violence in highly trained and experienced combatants sets up an ominous scenario for the communities to which these perpetrators return. Regardless of any public opinion denouncing combatants and torturers as mere animals who had a moral choice and chose wrongly, these individuals are in dire need of mental health rehabilitation and reintegration assistance. How do we untrain the trained torturer?

Untraining the Trained Torturer: FORNET as a Treatment Option

Following a conflict, perpetrators face numerous challenges to successful reintegration. Effective programs typically offer

formal education and vocational training and try to instill hope for the future (Mädl et al., 2010). Unfortunately, trauma symptoms and aggressive behavior can thwart successful attendance, participation, and completion of even the most comprehensive reintegration programs. The effectiveness of NET is not limited to rehabilitating the victims of organized violence. We thus are developing NET for forensic offender rehabilitation (Elbert et al., 2012) that aims to reduce both PTSD symptoms and appetitive aggressive behavior by recalling the experiences, as both victim and perpetrator, through narrative exposure. It helps the former combatant to anchor not only fearful and traumatic experiences but also positive feelings that might have been linked to various forms of aggressive behavior in the past. The role change from a combatant to a civilian is addressed specifically and reinforced. Additionally, visions for the future are developed to foster successful integration into society. Although there are early FORNET pilot trials (Hermenau et al., 2013), future studies need to focus on whether survivors on both sides of this cycle of violence can profit from evidence-based methods.

Conclusion and Future Directions

The concept of torture needs to be updated continually by neurological and psychological research and broadened to encompass the myriad of motivations and consequences of torture for all affected parties – victim and perpetrator alike. Torture utilizes tactics on a wide spectrum of violence: from directly aggressive techniques, such as beatings, limb removal, and waterboarding, to more indirect forms of aggression, including threatening or kidnapping family members and extreme periods of isolation. Regardless of the technique utilized, neurocognitively speaking, pain is pain, whether it is physical or social pain (Eisenberger et al., 2003).

One common, current justification for subjecting individuals to such pain involves the reasoning that accurate intelligence is procured through torture. Further neurological and psychological empirical investigations will help to expose the sinister and hedonistic motivations behind why torture persists: motivations that likely have little to do with gathering intelligence and a great deal to do with punishment and intimidation. Using research to inform and update international standards is a solid and necessary means of generating human right's improvements on the topic of torture. Furthermore, expanding the understanding of tyranny of torture beyond an event situationally and geographically specific to soldiers and prisoners in military conflicts tucked away in war-torn regions will acknowledge the needs of countless individuals coming off of less obvious battlefields. The sooner there is more widespread, official recognition of the intricate mosaic of factors that both motivate and result from torture, the sooner clinical treatment can be further empirically researched, funded, and implemented.

Torture: Legal Perspectives

Abstract

Torture is considered one of the most egregious of domestic and international crimes. Yet throughout history, state authorities have used torture and other forms of cruel, inhuman, and degrading treatment as means of interrogation and punishment. Accordingly, a number of legal frameworks have been developed to discourage physical and psychological torture and to encourage accountability for perpetrators. This article addresses the legal phenomenon of torture, including definitions, historical understandings, key cases, and emerging issues.

Introduction

This article addresses the legal phenomenon of torture, including definitions, historical understandings, key cases, and emerging issues.

Definition

At its most basic, torture can be thought of as the use of pain to elicit information from or to punish individuals in state custody. However, various legal approaches expand on that concept. Today, there are three frameworks that broadly address the legal phenomenon of torture: international humanitarian law, which considers torture in the context of armed conflicts; human rights law, which is concerned with the dignity and protection of individuals subject to state control; and criminal law, both international and domestic.

The human rights and international humanitarian law frameworks that address torture were largely developed and expanded in the aftermath of World Wars I and II. Shocked by revelation of the 'hidden horrors' of those wars – which ranged from forced disappearances to gassing to medical experimentation on live subjects – the international community came together in 1945 to create a global legal framework to prevent such horrors from reoccurring, and to assert a universal consensus on 'the supreme value of the human person' (Universal Declaration of Human Rights website). An intricate system of treaties, commissions, covenants, and protocols emerged, outlining a universal body of fundamental rights and freedoms designed to protect against future abuse, to provide for legal accountability, and (in some cases) to offer remedies for any wrongs.

With regard to international humanitarian law, also known as the law of armed conflict, the most notable prohibition against torture can be found in the Geneva Conventions of 1949. Torture is recognized as a 'grave breach' of the Conventions, and thus as among the most serious of war crimes. Within the human rights framework, the 1948 Declaration of Human Rights confirmed the existence of a foundational norm against torture, the prohibition of which is recognized as part of customary international law (custom being the primary source of international law).

Today, a growing number of international and domestic laws prohibit torture. The Convention Against Torture and Other Cruel, Inhuman or Degrading Treatment or Punishment (CAT) provides the most comprehensive definition of torture. Article 1 defines torture as "any act by which severe pain or suffering, whether physical or mental, is intentionally inflicted on a person for such purposes as obtaining from him or a third person information or a confession, punishing him for an act he or a third person has committed or is suspected of having committed, or for any reason based on discrimination of any kind, when such pain or suffering is inflicted by or at the instigation of, or with the consent or acquiescence of, a public official or other person acting in an official capacity" (CAT, art. 1). Notably, the Convention never defines cruel, inhuman or degrading treatment: it states only that such acts 'which do not amount to torture' are also prohibited when "committed by or at the instigation of or with the consent or acquiescence of a public official or other person acting in an official capacity" (CAT, art. 16, para. 1).

Drafted during the late 1970s and early 1980s and opened for signature on 4 February 1985, the Convention was signed by 25 countries within the first two months. Today, more than 150 states are parties to the Convention, reflecting near-universal condemnation of state-sanctioned abuse of individuals in state custody. According to Article 16 of the Convention, States Parties are obliged to prevent (and, presumably, to prosecute) acts of torture, as well as to prevent 'acts of cruel, inhuman or degrading treatment or punishment which do not amount to torture' committed by, or at the behest of, a public official (CAT, art. 16). Torture has been recognized by the world community as so despicable that it is categorized as one of only a few *jus cogens* crimes, meaning those crimes that are absolutely prohibited under all circumstances – no deviation from the prohibition against torture is permitted, even for states of emergency.

Despite the broad consensus against torture, how courts should interpret the crime's various elements has engendered significant debate. Issues have commonly focused on (1) whether the perpetrator was a state actor and/or was acting in an official capacity, (2) what is needed to demonstrate the perpetrator's 'intent' (e.g., whether all that is needed is evidence of an intent to perform the underlying act, versus evidence of intent to torture), and (3) the purpose for which

the offending act or acts occurred. Courts have especially grappled with how narrowly to construe each of these elements, and whether to focus strictly on the mental culpability of the perpetrator or to incorporate the subjective experiences of the victim. How these various elements are interpreted has a significant impact on the scope of the prohibition and whether anyone will be held legally accountable for its violation.

Historical and Theoretical Underpinnings

In order to fully understand what torture is from a legal perspective, it is important to know what the prohibition is meant to protect. Many scholars agree that the protection of human dignity is the underlying motivation not only for the prohibition against torture and other laws that prohibit ill treatment (Amnesty International USA, 2000), but also for the entire field of human rights and international humanitarian law (Kaufmann et al., 2011), and for domestic laws that undergird related harms, such as the US constitutional prohibition against cruel and unusual punishment (Simon, 2014). This concern with the protection of human dignity is evident in both case law and scholarship that considers the role of dignity in human rights protections. Thus, whenever one is considering possible interpretations of legal prohibitions against torture, it is critical to discuss the relationship between dignity and ill treatment, precisely because it is from the notion of dignity that all such prohibitions commence.

Arnd Pollmann provides a particularly helpful historical overview of the philosophy of human dignity. According to Pollman, human dignity was first acknowledged as an important concept during Roman Antiquity; this conception equated dignity with an exalted social status, as exemplified by the then-emergent term 'dignitary' (Pollmann, 2011, 246). The Middle Ages birthed a second conception, one intimately linked to Judeo-Christian theology, which reflected an idea of humanity as the 'pride of God's creation' and people as made in 'God's image' (Pollman, 2011, 246). Critically, while classical dignity resided in multiple forms of status as well as in virtuous conduct, the dignity that arises from the Hebrew concept of *kvod habriot*, or divine creation, applies to all human beings, regardless of their status or conduct, because of their creation in the image of God. Human dignity would become secularized during early modernity and the Italian Renaissance, as reflected in the writings of Immanuel Kant and Pico della Mirandola. For them, "As human beings we do not owe our dignity to the fact that we reflect a divine splendor but because we *ourselves* are capable of something great: of 'reason' and 'moral autonomy'" (Pollmann, 2011, 246). Yet an undercurrent of religiosity remained: René Cassin, a major contributor to the Universal Declaration of Human Rights, notably acknowledged the scriptural significance of dignity in his 1968 Nobel Prize acceptance speech (see Friedman, 2008).

The latest conception of human dignity, which is arguably the basis for the modern-day human rights regime, emerged in the aftermath of World War II. According to this conception, dignity is conditional; a person's particular circumstances dictate the extent to which he or she can live a dignified life. Accordingly, this conception birthed a perceived need for legally recognized and enforced rights to protect this critical human characteristic.

Pollman explains that per this fourth view, "although every human being—as a member of humankind—has an individual 'potential' to live a life in human dignity, the question whether we really are able to fully unfold this potential or capability is dependent upon the concrete circumstances of our life" (Pollmann, 2011, 250). Thus, dignity must be preserved and facilitated through law and related social norms.

Changing Tactics; Changing Laws

The ancient Greeks and Romans believed that physical torture was necessary to elicit truthful testimony for legal purposes. They also used torture as a form of punishment and as a means to discipline slaves. Depending on the location and era, practices included burning people alive, throwing people into pits, crucifixion, starvation, and more.

Such practices continued largely unabated and unquestioned for centuries. They also appeared across the world. Early European visitors to Asia reported witnessing torture, which was condoned by early Japanese and Chinese criminal codes. Spanish conquerors in the Americas tortured Indians in their search for gold, while English raiders in Africa tortured village leaders as a means to solicit the location of villagers, whom they would capture and sell as slaves. In the New World, 'witches' were also tortured, both as punishment and to encourage recantation of their presumed beliefs.

In response to the cruelties of the Inquisition and the barbarities of the Dark Ages, the eighteenth and nineteenth centuries witnessed a growing dissatisfaction with torture as a means of both punishment and information gathering. Foucault has credited two phenomena for this change. The first is the decline of punishment as a public spectacle. Whereas legal punishments used to be carried out in public, during the late 1700s and early 1800s punishment was increasingly driven indoors and/or underground; corporal practices ultimately gave way to an ever-growing use of imprisonment as a means to effectuate punishment. The second factor was a shift away from pain as a necessary component of punishment. Instead, the focus of punishment became one of control: control over the body, the mind, and the soul of the convicted (Foucault, 1975). These shifts resulted in many societies eventually outlawing torture.

Torture found an especially vocal critic in Cesare Beccaria, whose eighteenth-century treatise *On Crimes and Punishments* became a seminal work underlying the then-burgeoning anti-torture movement. But even his condemnation of the practice made little immediate impact on its use as a tool of inquisition and interrogation. Even as torture was increasingly criminalized, it remained a tactic used by police and other agents of the state; the practice just became more and more hidden. Accordingly, relatively unseen spaces within police stations and prisons – as opposed to public squares – became the predominate sites of modern-day torture.

In tandem with these changes, torture evolved from a practice focused almost exclusively on the body to one increasingly focused on the psyche. As has been pointed out by Darius Rejali

(taking an international perspective) and Richard Leo (domestically in the United States), western democracies in particular have increasingly employed psychological torture in place of its physical counterpart – engaging in practices that 'leave no marks' – in order to avoid international criticism for the torture of prisoners (Rejali, 2007; Leo, 2008). While both international and domestic laws expressly condemn psychological torture, the difficulty in gathering evidence of practices that leave few lasting and/or physical marks has meant that modern-day torture can be especially difficult to prove; because of this, accountability suffers, despite numerous studies that reveal that the psychological sequelae of torture often last longer than physical harms.

Torture has also evolved from a problem of active abuse – direct assaults on the body or mind – to a problem of deliberate indifference to the medical and mental health needs of prisoners and detainees. As US Supreme Court Justice Anthony Kennedy wrote in the 2011 Supreme Court case *Brown v. Plata*, borrowing from a Supreme Court case decided more than a century earlier, "A prison's failure to provide sustenance for inmates may … produce physical torture or a lingering death."

Key Cases

Despite such recognitions, the law has struggled to keep up with changing tactics. Several key cases help illuminate how the postmodern world conceptualizes torture.

The foundation for a modern-day, international jurisprudence of torture was laid in 1969 in the *Greek Case* (1969 Y.B. Eur. Conv. on H.R.), the first case ever brought for torture under the authority of the European Convention of Human Rights. In that case, the European Commission on Human Rights had to determine whether particular practices qualified as torture or as the lesser crimes of inhuman or degrading treatment. Ultimately, they declared that 'all torture must be inhuman and degrading,' but not all inhuman and degrading treatment is torture (Reidy, 2002, 11). Instead, they reserved the term torture for those extreme forms of inhuman treatment that have, as their 'purpose,' obtaining information or confessions, or inflicting punishment.

This seminal case is critical for establishing two of three dominant ways of conceptualizing the relationship between torture and cruel, inhuman, and degrading treatment. In the decision, a first understanding of the relationship – as a hierarchy that ranges from degrading treatment at one extreme, through inhuman treatment, and ultimately to torture – was emphasized. In this way, torture was conceived as an 'extreme' form of inhuman treatment. However, it was also conceived as one that requires an additional element to inhuman treatment, the proving of one of several prohibited 'purposes.' As the Commission explained in the *Greek Case*, "The word 'torture' is often used to describe inhuman treatment, which has a purpose, such as the obtaining of information or confessions, or the infliction of punishment, and it is generally an aggravated form of inhuman treatment."

This first, hierarchical approach was largely adopted by the European Court of Human Rights when, in 1978, it decided what would arguably become the most influential and foundational international case to address the prohibition against torture and cruel, inhuman, and degrading treatment. In that case, *Ireland v. United Kingdom*, the European Court of Human Rights debated whether the British authorities had tortured detainees in Northern Ireland. There, the court embraced the notion that the difference between torture and cruel, inhuman, and degrading treatment is merely one of degree when it concluded that "th[e] difference derives principally from a difference in the intensity of the suffering inflicted" (*Ireland v. United Kingdom*, para. 167). The Court ultimately held that the institutional treatment of detainees (which included wall standing, hooding, and depriving detainees of food and sleep) did not descend into torture. However, they concluded the techniques used on the prisoners were cruel, and therefore still illegal (*Ireland v. United Kingdom*, para. 167).

The European Court of Human Rights has been heavily criticized for its determination in the *Ireland* case that these practices were not torture, and especially for the reasoning upon which it relied to make its determination. As written by one critic, "[t]he concept of torture [embraced by the court] is one that requires extreme intensity of pain or suffering. It is significant in this regard that a subjective test, assessing the ill-treatment from the point of view of the victim, was not applied by the Court, which chose not to call witnesses. … By failing to engage with the victims' point of view, the Court overlooked a fundamental aspect of how to assess the severity of ill-treatment. It also merits attention that by defining torture primarily in terms of its physical intensity, the practice of torture is narrowly conceived by the Court so that it does not include acts that are not exceptionally [physically] brutal" (Cullen, 2008).

As Justice Evrigenis, who drafted a dissenting opinion in the case, further warned, such an objective perspective fails to encompass modern, predominately psychological forms, especially inventive techniques that have yet to emerge. As he noted, "Torture no longer presupposes [physical] violence, a notion to which the judgment refers expressly and generically. Torture can be practiced—and indeed is practiced—by using subtle techniques. … By means of new forms of suffering that have little in common with the physical pain caused by conventional torture it aims to bring about, even if only temporarily, the disintegration of an individual's personality, the shattering of his mental and psychological equilibrium and the crushing of his will" (*Ireland v. United Kingdom*, dissenting opinion of Judge Evrigenis).

Indeed, as has been written about in the contemporary era by law professor Richard Leo, it was precisely during this post–World War II period that interrogators increasingly favored psychological, 'rationalized,' and 'scientific' forms of torture that left no marks on victims and thus could more readily evade detection than their physical counterparts (Leo, 2008).

The tendency of the *Ireland* decision to overemphasize stereotypical, historic modes of physical torture and underemphasize psychologically based wrongs is especially prescient in the warning offered by Judge Evrigenis when the decision was released: "The notion of torture which emerges from the judgment is in fact too limited. By adding to the notion of torture the notions of inhuman and degrading treatment, those

who drew up the Convention wished, following Article 5 of the Universal Declaration of Human Rights, to extend the prohibition in Article 3 of the Convention [Against Torture]—in principle directed against torture—[to] other categories of acts causing intolerable suffering to individuals or affecting their dignity, rather than to exclude from the traditional notion of torture certain apparently less serious forms of torture and to place them in the category of inhuman treatment which carries less of a 'stigma'—to use the word appearing in the judgment" (*Ireland v. United Kingdom*, separate opinion of Judge Evrigenis).

Two decades later, in 1997, the United Nations Committee Against Torture (the body of experts that reviews state compliance with the Torture Convention's obligations) found that the especially harsh treatment of prisoners by Israel had violated the Convention Against Torture's prohibitions against cruelty *and* torture (Committee against Torture, Concluding observations of the Committee against Torture: Israel, para. 257). There, the practices under investigation included the 'standard' use of multiple prison-based practices, especially in combination: restraining individuals in painful positions, hooding them, exposing them to loud music, depriving them of sleep for prolonged periods, threatening them, shaking them, and using cold air to chill them. Two years later, Israel's High Court similarly ruled that certain interrogation methods used by Israel's General Security Service – including shaking, sleep deprivation, and use of the shabach position (the shackling of detainees in a painful configuration, typically while hooded and bombarded with loud music) – were illegal, although they avoided saying these practices amounted to torture (*Public Committee Against Torture in Israel v. Israel*, 1999, HCJ 5100/94). Instead, the Israeli High Court referenced *Ireland v. United Kingdom* to note that, in Ireland, similar interrogation techniques were found inhumane and degrading but not torturous and, thus, were barred only on that lesser ground. On that basis, the High Court ruled that the 'combination' of techniques gave rise to pain and suffering such that they should be prohibited as cruel and inhuman, although not as torture.

While the Israeli High Court largely reiterated the reasoning in *Ireland*, this case underscores a third major approach that courts have come to take when interpreting the relationship between torture and cruel, inhuman, and degrading treatment: a contextual approach, one more akin to a 'totality of the circumstances' analysis than a sliding scale.

The decade from 1990 to 2000, when these latter cases were decided, ultimately proved one of the most prolific with regard to interpreting international prohibitions against torture and other forms of cruel, inhuman, and degrading treatment. As these cases were proceeding through treaty-based courts and the court of public opinion, two new international tribunals were being formed. The first since Nuremberg and Tokyo to determine accountability for horrors committed in the context of specific conflicts, the International Tribunals for the former Yugoslavia (ICTY) and Rwanda (ICTR) emerged in the mid-1990s. Their chambers had to quickly establish a jurisprudence to expound upon the crimes articulated in their statutory law, which includes prohibitions against torture.

Through these tribunals, legal interpretations of torture expanded considerably. One of the ICTY's most notable torture-related cases was the *Furundzija* case (IT-95-17/1). There, the trial chamber defined torture as the "intentional infliction, by act or omission, of severe pain or suffering, whether physical or mental, for the purpose of obtaining information or a confession or of punishing, intimidating, humiliating or coercing the victim or a third person, or of discriminating on any ground against the victim or a third person. For such an act to constitute torture, one of the parties thereto must be a public official or must, at any rate, act in a non-private capacity, e.g., as a de facto organ of a State or any other authority wielding entity."

One of the most significant advancements to emerge from this tribunal – in both the *Celebici* (IT-96-21) and *Furundzija* cases – was recognition that rape can be a form of torture. The ICTR, in the *Akayesu* case (ICTR-96-4-T), also acknowledged that rape can constitute torture. Such findings went a long way to further international case law related to both sexual violence and torture, increasing the possibility for recognizing and ensuring accountability for harms committed against women and children.

The International Criminal Court, which came into being in 2002, has benefited from these earlier attempts to adjudicate torture cases. As the world's first permanent international criminal tribunal, the Court's stated purpose is to ensure accountability for the most serious crimes of international concern. Torture is expressly criminalized in the Rome Statute, the Court's founding treaty, as a war crime and crime against humanity. This relatively nascent court provides yet another forum for adjudicating claims of torture when domestic jurisdictions are unable or unwilling to act.

Emerging Issues and Practices

Despite these advancements, significant gaps remain in the law's ability to ensure accountability for torture, especially as abusive tactics continue to evolve. For example, while torture has traditionally been conceptualized as practices by state actors against individuals, modern warfare and imprisonment have increasingly been outsourced to private parties. Increased privatization has blurred the public–private divide and proven problematic, especially when private companies or individuals act only indirectly on a state's behalf.

There are also troubling signs that torture is re-emerging as a form of punishment. While the renewed use of torture for interrogation purposes has received significant attention following the 11 September 2001 attacks on the United States by al Qaeda operatives, the use of torture as a means of prison-based punishment has received less attention.

Prior to the eighteenth century, torturous punishments were common in Western justice systems (Foucault, 1975). However, the adoption of the Eighth Amendment's prohibition on cruel and unusual punishment was intended to forbid punishments that approximated torture in their degree of pain. The rejection of torture, along with a significant reduction in the use of capital punishment, was a primary motive underscoring the development of imprisonment as the predominate punishment

for serious crimes in the West beginning in the early nineteenth century. However, by the late twentieth century, a politicized fear of crime led to unprecedented increases in prison populations in the United States and in other Western countries (Garland, 2001; Simon, 2007), and the adoption of exceedingly long and harsh prison sentences. Chronic overcrowding (where prison populations sometimes exceeded 200% of capacity), combined with lack of adequate health care, led the US Supreme Court in *Brown v. Plata* (2011) to affirm a massive prisoner population reduction order under the Eighth Amendment and to warn that a prison's failure to provide adequate sustenance for inmates can produce physical torture.

Because no individual state actor is deliberately inflicting pain or damage in such cases, some adjudicators would reject overcrowding and neglect as examples of torture. However, since the results are a predictable product of deliberate incarceration policies, including a deliberate emphasis on security over health care and rehabilitation, many would argue otherwise. Thus, while torture has historically been an intentional instrument, contemporary torture can often be the product of 'deliberate indifference.'

The United States' prison-based use of extreme isolation has also been cited as a possible form of torture. Toward the end of the twentieth century, particularly harsh penal policies led most US states and the federal prison system to adopt a severe form of solitary confinement known as 'supermax' or a 'secure housing unit' in which prisoners are kept in near-total isolation – either alone or with one other inmate – for months, years, or even decades. Because sustained solitary confinement can lead to mental illness and suicide, many believe such extreme forms of incarceration should be considered cruel, inhuman, and degrading at a minimum, and possibly even torture.

Finally, empirical and theoretical research increasingly suggests the importance of taking into consideration victims' experiences in addition to a perpetrator's intent when defining torture. For example, there is growing recognition of the cumulative effect of abusive prison practices; empirical observations of prisoners' experiences strongly suggest that even when a single practice is not experienced as torture on its own, the collective use of abusive practices can add up to an overall experience of torture (Stover and Nightingale, 1985; Basoglu, 2007; Koenig et al., 2009).

The potential cumulative effect of ill treatment became particularly salient in the aftermath of evidence that the United States tortured detainees in the context of its post-2001 'war on terror.' For example, in 2009, a Pentagon official who was responsible for deciding whether detainees should be brought before military commissions declared that the practices used on a Saudi national held at the Guantanamo Bay Detainment Facility had amounted to torture. After reviewing his file, she chose not to refer the detainee's case for prosecution, declaring that "the techniques they used were all authorized, but the manner in which they applied them was overly aggressive and too persistent. You think of torture, you think of some horrendous physical act done to an individual. This was not any one particular act; this was just a combination of things that had a medical impact on him, that hurt his health. It was abusive and uncalled for. And … clearly coercive. It was the medical impact that pushed me over the edge [to call it torture]" (quoted in Woodward, 2009).

Despite several government and nongovernment reports documenting the torture of detainees in the twenty-first century, very few individuals have been brought to task for such abuse. The lack of successful prosecutions confirms the extent to which political will and diplomatic pressure remain critical stumbling blocks to ensuring accountability for this especially heinous crime.

Totalitarianism

Abstract

Totalitarianism was very much a twentieth century concept, and was applied primarily to Communist and fascist systems. This article examines the diverse interpretations of totalitarianism, and, in considering its defining features, explores the ways in which it is seen to differ from authoritarianism. Having analyzed the development of the concept, the concluding section considers its contemporary relevance and applicability to political developments in the twenty-first century.

Introduction

Totalitarianism was a major concept of the twentieth century. Yet both its meaning and its application were contested. While most political scientists believed that the term summarized well the key features of fascism (inc. Nazism) and Communism, historians, such as Alan Bullock (1998), Ian Kershaw (2000) and to some extent Richard Overy (2005) argued that the differences between Nazi Germany and the Soviet Union, even under Stalin, were sufficient for it to be misleading to use the same word to describe both. (In this article, and following a common convention, Fascism (upper case) refers explicitly to Mussolini's Italy, whereas fascism is a more general term to describe right-wing totalitarian systems. The term Communist (upper case) refers here to actual systems, to distinguish it from the ultimate ideal or goal of communism. The present tense is used for conceptual analysis, the past when referring to actual historical phenomena.) Although there unquestionably were significant distinctions between fascism and Communism, particularly in terms of the role and nature of ideology and the end goal, the dominant view nowadays is that the term is a useful shorthand way of describing a range of systems that, on balance, had more commonalities than differences, particularly in terms of their style and means. As will be demonstrated, while having much in common and in practice often overlapping with authoritarianism, totalitarianism is conceptually distinct.

This article begins by considering the defining features of totalitarianism, and then outlines the development of the concept in terms of its historical and intellectual contexts. Following this is a brief evaluation of the term. The final section concerns its relevance today and what this might be in the future.

Defining Features of Totalitarianism

As suggested by the root of the word, totalitarianism refers to a system in which control over the population is greater – closer to 'total' – than in any other type of political system. It is the most extreme version of subordination of the individual to the state, and to a questionable notion of the collective. It represents the politicization of all aspects of life. Totalitarian and authoritarian dictatorships have much in common, including a lack of respect for citizens' rights, for the public accountability of political elites, and for the rule of law. But a totalitarian dictatorship is distinguishable from an authoritarian one in several ways (see Linz, 1975, 2000 for a more detailed analysis).

First, ideology plays a far more significant role in the former than in the latter, even though many observers agree that ideology was less important in Fascist Italy and Nazi Germany than in Stalin's USSR and other Communist states. While totalitarian ideology often makes use of the past, particularly national traditions, it is fundamentally radical and future-oriented ('chiliastic' or 'teleological'), whereas authoritarian regimes typically focus more on the past and continuity.

Closely related to the first point is that the role of propaganda in totalitarian states is much greater than is typical in authoritarian states. Whereas the term propaganda has a negative connotation in liberal democracies, it has a positive one in totalitarian states. In the USSR, 'agitprop' (agitation and propaganda) was an important aspect of the Communist Party's role, while Hitler appointed one of his closest and most trusted colleagues, Joseph Goebbels, to head the Ministry of Propaganda and Enlightenment. Simple slogans – such as 'Credere, Obbedire, Combattere' (Believe, Obey, Fight) in Fascist Italy; 'Arbeit macht Frei' (Work Liberates) and 'Ein Volk, ein Reich, ein Führer' (One People, One Empire, One Leader) in Nazi Germany; or 'Za Rodinu! Za Stalina! Za Mir! Za Kommunizm!' (For the Motherland! For Stalin! For Peace! For Communism!) in Stalin's Russia – were intended to convey the state's message straightforwardly but powerfully to the populace.

Totalitarianism is also often overtly exclusionary, and arbitrarily identifies particular minority groups as 'enemies' of the state and/or the people (e.g., Jews, gays, and communists in Nazi Germany; 'the bourgeoisie' and kulaks – rich peasants – in Stalin's USSR; Roma, gays, socialists, and communists in Fascist Italy), for whom life could become literally unbearable. In some cases, citizens could, if they chose to, renounce their allegiance; this applied to membership of a political party that was considered by the authorities to be hostile to the totalitarian system, but if one were Jewish or Roma or gay/lesbian, such options were not available. And sometimes, as in Stalin's USSR, social class labeling by the state could be highly arbitrary anyway.

This high level of apparent arbitrariness is related to another distinguishing feature of totalitarianism: its use of terror. Thus, the Nazis are remembered for the holocaust and concentration

camps and Stalin for the labor camps administered by the GULag. The exact number of deaths that resulted from such state terror is disputed, but undoubtedly runs into many millions. In terms of the *proportion* of the population who died at the hands of a totalitarian system, however, Pol Pot's Communist Cambodia was the worst of all.

In theory at least, the single political party plays a more prominent role in a totalitarian regime than in an authoritarian one. In the latter, it is often the military or a small clique that controls the state. There were unquestionably military elements integral to the rule in totalitarian states. For example, Hitler, Mussolini, and Stalin sometimes appeared in military uniform, while their more familiar party uniforms were clearly influenced by military ones. However, the military was ultimately subservient to the party.

Totalitarian systems are often held to be distinguished from authoritarian ones in terms of the image of the leader. The leading totalitarian systems all had putatively charismatic leaders – a feature found far less often in authoritarian systems – although some have challenged the notion that the charisma was real, rather than merely the result of artificial personality cults promoted by the state authorities, especially in the case of Stalin. But it must be acknowledged that many Soviets, Germans, and Italians did hold their leaders in awe and mourned their passing. The image of strong leaders was reflected in the terms used to describe them in official propaganda; *der Führer*, *Il Duce*, and *Vozhd'* all connote *the* ultimate leader or chief in German, Italian, and Russian, respectively. Citizens were often expected to show respect for the leader in the form of salutes, as in 'Heil Hitler' (Hail Hitler) in Germany; in Italy, the Fascists adopted the 'Roman Salute,' and by the 1930s were requiring citizens to use this instead of the 'bourgeois' and 'unhygienic' handshake. The leader was often portrayed as a kindly father figure to the nation; good examples include China's Mao Zedong, Vietnam's Ho Chi Minh, and North Korea's Kim II Sung.

Authoritarian systems typically permit a limited amount of pluralism. This might be in the form of (often manipulated) competitive elections. In contrast, totalitarian systems do not permit pluralism, and even forbid overt differences of opinion within the party.

It has been argued by Linz (1975, 2000) that citizen mobilization is typically low – neither extensive nor intensive – in authoritarian systems, but high in totalitarian ones. The totalitarian state wants its citizens to demonstrate their loyalty in a much more public and overt way than does the authoritarian state. It was because Communist systems expected their citizens to express devotion to the state that what might appear to an outsider to be a symbolically trivial gesture made by the Hungarian leader in 1961 caused such a stir. Until then, like other Communist states, Hungary claimed to assume that 'if you're not with us, you're against us'; but in that year, János Kádár reversed this, saying that in future the assumption would be that 'if you're not against us, you're with us.' In terms of citizen devotion to the cause expected by the authorities, both fascist and most Communist states even encouraged women to bear more children, so as to increase the population and hence the strength and size of the totalitarian state.

While most authoritarian systems do not seek to control citizens' personal beliefs, notably their religion, Communist totalitarian states did. Indeed, James Gregor (2012) has argued that the totalitarian ideology was itself a form of religion – even where there was official commitment to secularization – with its focus on selfless sacrifice, messianism, and a glorious future. This said, it should be noted that the fascist and Communist approaches to the organized church were quite different, and there needs to be nuancing on this variable. In Japan, the fascists promoted 'State Shintoism,' which essentially linked the state with the country's traditional religion and nationalism. Mussolini knew that he needed to reach a *modus vivendi* with the powerful Roman Catholic Church in Italy, and so designated it as the sole state religion (i.e., other religions were banned). Hitler had a complex approach to religion, wanting to ban the Old Testament because of its Jewish connotations, treating Catholicism more harshly than Protestantism, but advocating a 'positive Christianity.' The Communist approach to religion was also complex in practice. As Marxists, Communists were atheists who saw religion as 'the opium of the people.' But only one Communist state – Albania, in 1967 – ever formally banned religion. Stalin was initially hostile to the Church. But after the Soviet Union was compelled by the Nazis to enter the Second World War (1941), he realized that he needed to maximize the nation's support for what the Communists called the 'Great Patriotic War,' and so became far more tolerant at least of the main Russian Church (Russian Orthodoxy). In return, the Church was to encourage patriotism and support for the Stalinist system and war effort.

Another area that the totalitarian state seeks to control and harness for its own use far more than does the authoritarian state is art and architecture. In Stalin's USSR, for instance, artists were to abide by the tenets of 'socialist realism,' while architects in Fascist Italy, Nazi Germany, and Stalin's Soviet Union were expected to design state buildings that were often on a grand scale and very solid, yet largely devoid of ornamentation. This approach was intended to symbolize a combination of strength, durability, functionality, optimism, and a commitment to the common people (see e.g., Affron and Antliff, 1997; Lahusen and Dobrenko, 1997; Krier, 2013).

Authoritarianism relates primarily to a political system, and there is no necessary implication that the state is heavily involved in the economy. In contrast, most theorists of totalitarianism maintain that, while Communist states generally controlled the economy much more than did the fascist states and introduced almost complete state ownership, the overall level of state interference in and interaction with the economy was much higher in all kinds of totalitarian states than in authoritarian ones.

The leading totalitarian systems were expansionist. Thus, the Nazis advocated more *Lebensraum* (living space) for Germans, and invaded Czechoslovakia and other European states in this context; the Italian Fascists made various irredentist claims, and invaded Abyssinia (now essentially Ethiopia), partly on the grounds that a superior nation needs to demonstrate its strength if it is not to fall into decline; while the Japanese fascists invaded Indochina and parts of China. Although Stalin theoretically rejected overt communist expansionism in the 1920s, when he promoted the concept of

'socialism in one country,' he took advantage of the Second World War and its aftermath to extend Soviet power not only into the Baltic States (Estonia, Latvia, and Lithuania) and Moldavia (now Moldova), which were incorporated into the USSR, but also into Central and Eastern Europe. It should be noted that most of the smaller countries that have also been described as totalitarian did not have such expansionist policies, however; examples include Laos, and Albania.

Finally, but importantly, totalitarianism is sometimes seen as a particular and distorted version of advanced modernity, and as a phenomenon that did not and could not emerge until the twentieth century – points that do not apply to authoritarianism. This observation about totalitarianism's relative newness is made mainly because it was not until the last century that the technological means for very high levels of control of populations existed. With the rapid development of the means of mass communication, notably the radio and cinema, citizens could be subjected to a constant barrage of state propaganda in a manner that was not possible in earlier kinds of dictatorship. This, together with the great emphasis placed by totalitarian regimes on state-run purposive education for all, meant that the state's capacity for indoctrination ('thought control,' pejoratively known as brainwashing) reached qualitatively new levels.

Although there have been several comparative analyses of totalitarianism, the most widely cited remains that of Carl Friedrich and Zbigniew Brzezinski (1956; amended version 1965). In the earlier edition, these authors identified what they considered to be the six salient features of totalitarian regimes. These were an official, all-embracing and chiliastic ideology; a single mass party, typically led by one man (the dictator); a system of terroristic police control (high levels of apparently arbitrary coercion); a near-complete monopoly of the means of communication; a near-complete monopoly of the means of armed combat; and central control of the entire economy. In the second edition of their book, this list was supplemented to include a commitment to expansionism and the administrative control of justice.

Another well-known analysis is that of Hannah Arendt (1951), a political philosopher and social theorist after whom a research institute on totalitarianism, founded in 1993 and based in Dresden, is named. Arendt argued that totalitarian systems often commanded widespread support in their early stages, since they offered security, comfort, and employment for most citizens in post-war and crisis contexts, as well as national pride following what was perceived to be their country's national humiliation (at least in the cases of Nazi Germany and, albeit to a lesser extent, Fascist Italy). But over time, totalitarian systems also lead to increasing atomization of the citizenry, to such an extent that even members of one's family may not be trusted. One of the saddest aspects of Stalinist Russia was that the authorities held up as a model citizen a teenage boy, Pavel Morozov, who allegedly reported his own father for opposing Stalin, and was then killed by his family – several members of which were then themselves executed by the state. While recent research suggests that much of the Pavel Morozov incident was a fabrication by the Soviet authorities, there is no question that the state used the story to encourage Soviet citizens to denounce each other; this is quintessential totalitarian atomization. For Arendt, one of the worst aspects of atomization was that it stifled all independent citizen initiatives.

It must be noted that some authoritarian regimes have displayed some of the features of totalitarianism outlined above. The use of state terror against alleged enemies of the state was a significant feature of General Pinochet's rule in Chile, for example. Moreover, some of the alleged differences are highly disputed, such as that totalitarian systems have charismatic leaders, which authoritarian systems do not. Nevertheless, if all the variables are combined, there really remain some important differences between authoritarian and totalitarian systems. This is not to deny that they are related, however; they clearly are, and some see totalitarianism as simply an extreme version of authoritarianism. In many ways, the approach adopted by Linz already in the 1960s, which is to see authoritarianism as a midway point along a continuum between democracy and totalitarianism, is the most useful way of conceptualizing these types of system.

The Development of the Concept

The concept of totalitarianism can be traced back to 1920s' Italy; from 1925, Mussolini himself used it in a positive way to describe the Italian Fascist system. But the term was not in common usage in English until after the Second World War. As Archie Brown (1999) points out, one of the first to alert the public to the differences between traditional authoritarian and the new totalitarian regimes was not a social scientist, but the novelist George Orwell. In *Animal Farm* (1945), Orwell focused on the hypocrisy and undemocratic nature of Communism, while in *1984* (published 1949), he highlighted the horrors of a society in which the notion of the ends justifying the means was taken to new extremes, and in which political elites could manipulate mass consciousness through high technology indoctrination. In this nightmare world, the goal of achieving a better society in the future was seen to override the concerns of ordinary individuals in the present.

Within the social sciences, it was primarily a number of scholars of German or East European origin who elaborated the concept and produced comparative analyses of its application in practice. While Arendt and Friedrich were of German origin, Brzezinski had Polish roots. These analysts, or members of their families, had often experienced the horrors of totalitarianism first hand. While fascism appeared to have been defeated by the end of the Second World War, Stalin's USSR became stronger, with much of Eastern Europe coming under direct Soviet influence for the first time. One of the objectives of many scholars of totalitarianism was thus a normative one. They sought not only to explain what it was and how it had arisen, but also to demonstrate that it was inherently evil, and why the West should resist it. In the climate of the early Cold War between liberal democracy and Communism, such normative analyses found considerable resonance and support, especially in the USA.

But the term began to lose some of its popularity by the 1960s, even in the United States (see Friedrich et al., 1969). Many now felt that it was inappropriate to use the same term to describe the USSR under both Stalin and Khrushchev, for

instance, especially since the latter was by the early 1960s referring to his predecessor's crimes against the Soviet population. The Hungarian leadership's liberalization in the 1960s, briefly alluded to above, was another reason why many began to question the continuing validity of the concept of totalitarianism to describe Communist systems. The term became even less fashionable in the early-1970s, when the relationship between the Soviet bloc and the West entered a more constructive phase, known as *détente* (lit. a reduction in tension). At about the same time, scholars such as Jerry Hough in the USA and Gordon Skilling in Canada began publishing articles and books, based on solid research, which suggested that there might be a limited form of pluralism emerging in the Soviet Union.

While the popularity of the concept was declining in the West, Jacques Rupnik (1988) maintains that, in the aftermath of the Warsaw Pact invasion of Czechoslovakia of 1968, many intellectuals in what is nowadays known as Central and Eastern Europe began to use the term totalitarianism in a different way from those that had earlier been favored by so many Western observers. These East Europeans tended to focus less on political institutions, and more on the political use of the language – not merely to indoctrinate citizens, but to limit the scope of discussion (discourse) and hence the parameters within which thought could roam. They also criticized the methods used by totalitarian – here, basically meaning Communist – regimes for suppressing knowledge of the past that did not suit those regimes. Totalitarianism was thus seen to be intent on destroying those historical memories, and hence the aspects of culture that did not suit the rulers.

The Usefulness of the Concept

As noted above, the concept of totalitarianism has been criticized for over-generalization about the regimes that some analysts consider too diverse to be grouped together under one heading. To Italy and Germany, for instance, could be added several other countries that were fascist or quasi-fascist at some point during the 1930s and 1940s, including Croatia, Hungary, Japan, and Romania. Among Communist states, there were substantial differences between, for instance, the *relatively* liberal and outward-looking Yugoslavia or Hungary and the far more orthodox and isolationist Albania or North Korea (it is worth noting that countries such as Croatia, Hungary, and Romania have been classified by analysts as both Communist and fascist totalitarian systems at different points in their histories). Certain aspects of the Friedrich and Brzezinski model, such as expansionism, did not apply to these smaller countries – although it must be acknowledged that Brzezinski distanced himself from the second edition of their book. The point also pertains in some cases to significant changes within one country over time; this lack of dynamism in Friedrich and Brzezinski's approach was strongly criticized by Karl Dietrich Bracher (1981). Moreover Slavoj Žižek has used the term totalitarianism so broadly, to include inter alia neoliberal democracies, that there is a danger of the term losing precision. Is the concept therefore too amorphous and too contentious to be useful?

There is considerable variety among systems usually labeled 'liberal democracies' – presidentialism, semi-presidentialism, and parliamentarism; federalism and unitarism; and so on – yet few would advocate abandoning the term liberal democracy; most accept that there is more in common between these systems than there are differences. Much the same can be said of totalitarian systems. Discarding Žižek's absurdly broad usage, which represents extreme conceptual stretching, the term totalitarianism is particularly useful if it is used as an ideal type, rather than as a model. The former is taken here to mean a pure form of an idea, against which actual regimes are measured. While the concept of a model has diverse meanings, it refers here to an attempt to encapsulate the salient features of a given system or type of system in a structured, schematic way. If totalitarianism is used as an ideal type, it is possible to say that a given country is more totalitarian or less totalitarian than another, or more totalitarian at one time than at another time. Using totalitarianism in this way overcomes the criticism that it is statically descriptive and lacks any internal dynamism.

Totalitarianism Today and Tomorrow

Most totalitarian systems have long since collapsed, for complex and diverse reasons that cannot be explored here. The major post-totalitarian systems soon adopted laws designed to ensure that totalitarianism could never emerge again in these countries. For example, it is illegal in Germany to display the swastika or deny the Holocaust; the 1947 Italian Constitution made it illegal to attempt to reorganize the Fascist Party; while Yeltsin banned the Communist Party in Russia in 1991 (although the Russian Constitutional Court later rescinded this decision and the Communists continue to perform reasonably well in Russian elections).

The concept of totalitarianism has experienced a limited resurgence of popularity since the collapse of Communist power in 1989–91, especially among Central and East Europeans. When the Communists were in power in that region, it was generally forbidden to suggest publicly that they were totalitarian dictatorships. Indeed, most of these countries officially claimed to be 'socialist democracies.' Since the early-1990s – and in some more liberal Communist states even before that period – many critics of the old regime have regularly and publicly referred to their countries' pasts (until the late-1980s) as totalitarian. Although this usage of the word is often loose and little more than a term of abuse, it has led some scholarly analysts to argue that the concept may have been abandoned prematurely during the later stages of the Cold War (see Siegel, 1998), and that, liberalization phases and certain changes notwithstanding, most Communist states remained fundamentally totalitarian until their collapse.

But does the term still enjoy currency elsewhere? Post-modernists such as Jean-François Lyotard were claiming in the late-twentieth century that the world is now moving on from the universalistic or grand theories – 'metanarratives' in his terminology – such as Marxism. Since 'grand theory' was the basis of Communist – and to a lesser extent fascist – ideology, which has been seen as such a distinguishing feature of

totalitarianism, it might be assumed that totalitarianism is a thing of the past. Although most commentators agree that there are no overtly fascist regimes at present (2013), some analysts (e.g., Christopher Hitchens) and politicians have refered to the rise of Islamic fundamentalism and various highly authoritarian regimes in predominantly Muslim states as Islamofascism. In 2005, US Secretary of State Condoleezza Rice – a Soviet and Russian specialist, thus well aware of the debates on totalitarianism – described Iran as a totalitarian state. Other Muslim states that have at various times been labeled totalitarian include Afghanistan (under the Taliban), Iraq (under Saddam Hussein), Libya (under Muammar al-Gaddafi), and Syria (under Bashar al-Assad). Moreover, there remain five Communist states (PR China, Cuba, DPR Korea, Laos, and Vietnam), and these are sometimes still described as totalitarian. With the exception of North Korea, however, there have been such significant changes in these Communist states in recent years that the label is misleading and inappropriate. In line with changes in the contemporary world, the Economist Intelligence Unit's *Democracy Index*, which was first published in 2007, does not even include totalitarianism as a regime type (its four categories are full democracy, flawed democracy, hybrid, and authoritarian).

Yet, we cannot be certain that totalitarianism is all but dead. It would be reassuring to feel confident that humanity learns from past mistakes; however, to be so would be naïve. Moreover, while it is true that globalization and the internet are rendering it ever more difficult at present for individual governments to control their populations in ways they sometimes did in the twentieth century, it is quite possible that governments will catch up with the technological revolution and harness it to new totalitarian objectives and styles. A number of states already censor the internet, and this practice could well increase in the future. Although many analysts point to the rise of social media such as Facebook and Twitter as developments that render state control of citizens more problematic, and cite the role of such media in rapidly inciting mass unrest in countries in which regimes have been either threatened or actually toppled (e.g., Myanmar and several Middle Eastern states during the so-called 'Arab Spring'), it would be unduly optimistic to assume that states will not attempt to control these too in the future. And, while the almost exponential increase in the use of CCTVs, in accessing individuals' bank accounts, and in listening to private telephone conversations may well be primarily a function of states' attempts to reduce crime rates and increase the public's security, the acclimatization of citizens to such developments also opens up possibilities for state elites so inclined to tend toward more totalitarian control.

Moreover, the rise of the extreme right (neo-fascism) in several European countries – including Austria, France, Germany, and the UK – since the 1990s means that it would be ingenuous to consign totalitarianism to the rubbish bin of history. Even state agencies in some countries have recently in some ways softened their approach toward totalitarianism. Thus, the Hungarian Constitutional Court revoked a ban on Communist and fascist symbols in February 2013. While this led to considerable public outcry, the Court defended its position in part by reference to November 2011 and April 2012 decisions by the European Court of Human Rights to permit the Red Star, on the grounds that it did not represent a symbol of tyranny, and that banning its use represented an unjust limitation on freedom of expression.

Given the points made in the previous two paragraphs, and while it may well be in a new form, since it would have to engage with a world that is very different from that of the early-to-mid-twentieth century, totalitarianism may yet rear its ugly head again. If it does, it is to be hoped that the collapse of both fascist and Communist systems in the past prove that the power of the state to control and mold the human spirit and suppress the desire for freedom can only ever be limited and temporary. Unfortunately, temporary does not necessarily mean short-lived.

Totemism

Warren Shapiro, Rutgers University, New Brunswick, NJ, USA

Abstract

'Totemism' is a word widely used, not only by anthropologists but also in popular discourse. The arguments are made here that if the word points to anything in the real world, it is to a relationship between systems of social divisions and their analogous objectifications; the objectifications may or may not be animal forms; and when they are, a relationship of consubstantiality may or may not be posited between individuals and their objectification.

A book could be written about the myriad ways in which the term 'totemism' has been bandied about in the history of anthropology. The famous French scholar Claude Lévi-Strauss did just this in his *Totemism* (Lévi-Strauss, 1963), only to resurrect the term's initial significance as a religious association with animal forms. What Lévi-Strauss, without due acknowledgment to Alexander Goldenweiser (Shapiro, 1991), added was an analogical link between these forms and certain social divisions found widely in the tribal world, such that

> animal species A:social division 1::animal species B:social division 2::animal species C:social division 3 …

Current thinking on totemism has mostly accepted the Goldenweiser/Lévi-Strauss theory. But the main problem with this position is that it has become unmoored from the ethnographic bases from which the term originated, with the counterproductive result that this term has taken on a life of its own. It needs to return to its roots, which lie in native North and South American and especially aboriginal Australian ethnography – more particularly with respect to social divisions that anthropologists conventionally call 'clans.' This label too has become essentialized, pointing, allegedly, to units in which kinship links among members are assumed but not demonstrable.

Recent reexaminations of the data from all the three geographical areas noted, which are associated with clans, indicate that kin connections are neither demonstrable nor assumed; that the social divisions in question sometimes have relationships with their objectifications – which, as we shall see, are not accurately rendered as animal species – but are of an entirely different order. Thus Tooker (1971) tells us that in native North America "there is often evidence that the members of the clan consider themselves not linked by reason of the relationship through their mother or father, as the case may be, but by reason of their relationship to a clan bundle or fetish and its associated rights." As for South America, more particularly Amazonia, Murphy (1979) has noted "a kind of descent that incorporates within itself qualities of timelessness." This needs exemplification. In Northwest Amazonia there are local clans whose male members live permanently on landed estates supposedly created in a mythical period, and whose sisters move to their husbands' estates with marriage. This sounds like textbook 'patrilineal descent,' except for the salient consideration that the mythical period is not linked lineally to the present time. Rather, it is held to be recreated in all-male ritual, wherein the participants are said to be consubstantial with Creative Beings and whose purpose is to recreate the world (Goldman, 2004; C. Hugh-Jones, 1979; S. Hugh-Jones, 1979; Jackson, 1996). Thus, far from being a relationship of descent, the tie among clansmen might more accurately be described as a relationship of *anti-descent*, a denial of the decaying influence of time – in short, an assertion of immortality through consubstantiation with Creative Beings. Such an assertion, far from being arcane, is nothing less than the central tenet of Christianity. Northwest Amazonian belief differs primarily from Christianity, in that consubstantiality is segmented by clanship, not unified through a monotheistic doctrine.

An especially remarkable illustration of all this in Amazonia is provided by the Bororo of Central Brazil. Here the number of clans is fixed at eight; and if a clan is in danger of becoming extinct, its membership is replenished by changing the affiliation of a sufficient number of individuals of other clans – again, as if the influence of time must be denied. The same denial is apparent in the principle of clan affiliation, which is not through descent but through naming: an individual is a member of the clan that owns his/her name. This is normally the mother's clan, but the Bororo deny that clan members are all descended from a single ancestor or ancestress, i.e., that their relationship is carnal. As if to clinch the argument, an individual gets the names of certain kin, and for several days before the conferral of the name, these kin are expected to refrain from sexual relations (Crocker, 1985). Again, there are Christian parallels: Jesus is sometimes referred to as The Word (i.e., the name), his life said to be 'without sin' (i.e., sexless), and his quintessentially creative act was performed not through sex but through male violence.

This opposition of creation through sex and creation through violence is, in fact, widespread. This is particularly clear in ideologies of sacrifice, nearly always a male monopoly, in which the man's ability to 'give death' is very frequently contrasted with the woman's ability to give birth and the former is held to be superior (Jay, 1992). In many parts of native America, war captives were held to be the 'children' of their captors, only to be put to death by their 'fathers' (Conklin, 2001; Rosaldo and Atkinson, 1975; Santos-Granero, 2009). In the case of the Aztecs, such sacrifice was held to be necessary to renew the world itself (Read, 1998). There is more than a passing resemblance between all this and the New Testament narrative of the crucifixion.

Moreover, there is a link between violence and naming: both are assertive acts. Hence in the Old Testament, God creates the world by the latter method but in the New Testament he recreates it through the former. Hence we should not be surprised that both procedures are widely considered to be antithetical to, and superior to, sexual generation (Noble, 1992; Shapiro, 1995). Nor should we be surprised at the blatant sexism of religious ideologies around the world – as if men, by one or another kind of assertion, can provide enduring life, as contrasted with the ephemeral life provided by women.

The same elements can be seen in aboriginal Australian clan totemism. Here, as in Northwest Amazonia, there is no notion of descent in the strict sense but rather consubstantiality with mythical beings, who supposedly created the world. Here too is the all-male cult, in supposed imitation of the very acts of creation. And these acts usually employ one or another sort of assertion. Creation occurred, in native theory, when mythical creatures brought something into being by calling its name, or by their bodily movements, or by voluntarily divesting themselves of parts or all of their bodies that are said to have become features of the landscape. They sometimes have sex – there are female and hermaphroditic as well as male beings – but it is the assertive acts, not the erotic ones, that are held to be creative (Morton, 1987a,b; Munn, 1970). This is so much so that, when talking about human reproduction, aboriginal men often emphasize the dream encounter – usually by the father – with a Creative Being, who is then held to enter the mother and be reinstantiated in the child. Several generations of anthropologists have concluded – quite wrongly – from this sort of testimony that the native Australians are ignorant of physical paternity (Shapiro, 1996). One might just as well argue – with equal absurdity – that Roman Catholics or Orthodox Christians are similarly ignorant, for in these traditions too there are ideologies of rebirth in which a 'father' acts as intermediary between the world of the flesh and that of the spirit.

The degree to which theories of totemism were founded upon classic studies of aboriginal people in the Central Desert of Australia can hardly be overstated. Freud (1918), seizing upon (1) the fact that in some aboriginal Australian populations clans are *exogamous* i.e., a person may not marry his/her clansmate – upon the supposed descendant/ancestor relationship that the individual has with his/her totem; (2) that in some of these populations, a man may not kill a present-day animal representation of his totem; and (3) the view, widely held at the beginning of the twentieth century, that aboriginal Australians represent the 'earliest stage' in human history, argued that at this earliest stage, the central human concerns were the denial of the murder of the 'primal' father and the renunciation of the desire to mate with one's mother.

This Oedipal theory of the origins of human sociality does not farewell in the light of present knowledge. Although in some parts of aboriginal Australia clans are exogamous, this is not, as noted, the case everywhere on the continent; and in other parts of the world this may or may not be the case. In any case, with a *patrifilial* (father/child) principle of recruitment, plus exogamy, a man's mother will be a member of another clan. The argument could be made – and was made by scholars writing around the same time – that the earliest form of clanship was based on a *matrifilial* (mother/child) link, but there is no real evidence for this. And even if such evidence could be found, the question could still be raised as to why the sexual prohibition pertained to a number of women and not just to the mother. In any case, there is now unmistakable evidence that people, far from desiring sex with close kin, are instead neurologically inhibited from copulating with others raised from early childhood in the same locale (Wolf, 1993).

A further objection to Freud's theory has already been considered, viz., the relationship of consubstantiality that exists between an individual and his/her totem. This is especially clear in the most famous case, that of the Aranda (now rendered as Arrernte), where an individual is said to be a reincarnation of a Mythical Period being, with the father, as noted, only an intermediary in the act of spiritual transmission (Spencer and Gillen, 1899). One can see here, incidentally, how western observers were misled into thinking that aboriginal Australians are ignorant of physical paternity: the father's dream experience, which has to do with the generation of the spiritual person, logically ignores it. But we now know that the Arrernte also hold, as we do, that the physical person is a product of sexual relations (Austin-Broos, 2009).

A remarkable consideration here is that six male anthropologists have studied the Arrernte, and all six have been given an account of spiritual generation, a male monopoly. By contrast, two female anthropologists have interviewed Arrernte men, who proceeded to restrict their discourse to sexual creation, probably because ideas concerning spiritual creation are secreted from their own women.

As for not killing a current representative of the totem animal, this is a mixed bag. The prohibition has been reported for some parts of aboriginal Australia but not for others; and when killed, the totem animal may or may not be accorded special respect, such as an apology to its spirit. Still another variable has to do with which animals may or may not be killed. Thus in my own fieldwork, a 1000 miles to the north of the Arerrnte in Australia's monsoonal tropics, I found a serious ban on killing applying only to rock pythons, whose archetypical form has a special significance. Yet one man I talked with, apparently extending this sort of prohibition, suggested that men associated with other totems might be upset if one of the current representatives of any of the totems were killed.

Another classic attempt to find 'original' humanity in aboriginal Australian materials was made by Durkheim (1915). Durkheim argued that clan totemism is a projection onto the external world of social relations, of what he, and we, call 'society.' Note that this label, suggesting as it does an entity apart from human beings and their relationships, is itself a projection – what has been called a 'reification' (Berger and Luckmann, 1967). The idea in itself that religious notions stem from human affairs is reasonable enough, and it can lead to empirically testable propositions (Swanson, 1964). But Durkheim took as the elements of sociality in aboriginal Australia the clans themselves – a position true of a very great deal of theorizing both before and since he wrote, but which is utterly untrue to the facts. We now know that although these units are linked to territories, this linkage

is purely ideological, rather like the attention paid in Judaism, Christianity, and Islam to Jerusalem and its environs; the effective local groups on the continent are networks of bilateral kin, with special emphasis on the tie between a man and his in-laws (Hiatt, 1965; Peterson, 1970; Shapiro, 1973). The clans, in short, are not localized, despite their iconic link to locality.

Attention should be paid to the link between aboriginal Australian clanship and male bloodletting rites – more generally, to a man's progress in spiritual life. The most startling of these rites to a western observer is what has been called *subincision*, practiced by the Arrernte and many of their neighbors. Here a youth is secreted from the main camp and the eyes of women and children, and his penis is split lengthwise, so as to expose the urethra. Although the significance of subincision has been debated by anthropologists, it is clear that one intention is to endow the boy with a pseudovagina. He is thus a hermaphrodite of sorts, capable of a kind of reproduction that is independent of women. More specifically, he is now able to participate with men already subincised, in rites designed to increase the supply of animals associated with the pertinent clan, and in ceremonies in which younger boys are reborn as men. The reproductive symbolism of both kinds of rituals is plain as day. In some rites of the former sort, a subincised man or several men enter a large crevice which has been carved into the ground and which is likened to the female reproductive area. The man or men next re-open their subincisions, deliberately shedding blood, which is often regarded as the female contribution to the fetus. Then, having adorned their heads with white clay and having allowed it to congeal, they cause their bodies to quiver, one result of which is to spread particles of dried white clay into the crevice (Róheim, 1945, 1971; Spencer and Gillen, 1899; Strehlow, 1947). One hardly has to be a doctrinaire Freudian to argue that the crevice is (seen as) a vagina, the quivering body as a penis or penes in the course of copulation, and the particles of white clay as seminal emissions. Similarly, Hiatt (1971) has called attention to the widespread occurrence of what he calls 'uterine rites' in transforming aboriginal Australian boys into men. In these, men secreted from women, form objects which are likened to the female reproductive area. In the most remarkable instance, men whose penes have already been cut, form a line and spread their legs as widely as possible. The boy then moves through the line, to emerge from it as a man, newly born from a collective male vagina.

Although, for obvious reasons, it is subincision that has gained the most attention from anthropologists, there are comparable hermaphroditic rites elsewhere in aboriginal Australia – and, indeed, in other parts of the world. Further north on the continent, boys are first circumcised and the blood that flows from the womb is expressly likened to vaginal blood, which is as noted, the supposed female contribution to the fetus. Then, a few years later, they are scarified in the upper arm to create a pseudovagina, and this wound, like the Arrernte subincision, is periodically reopened, not with a view to increasing the supply of animals as this is a much better-watered area, but to enable the process of transformation – the rebirth – from boyhood to manhood. East of New Guinea much the same ideology is effected when men ritually gash their penes with the claw of a crab (Hogbin, 1970). And it appears that scalping among the Plains Indians and the blood of warfare in parts of Africa are associated with a similar set of notions, though here the blood is taken not from oneself but from another (de Heusch, 1982). What is remarkable about this last set of cases is the coupling of ritual hermaphrodism with violence, as noted above, with both being considered higher forms of creation than sexual relations.

That what is involved here is a distinction between physical birth and spiritual rebirth is made even clearer by another procedure which occurs both among the Arrernte and further north, in connection with all-male ritual. After a boy is introduced to ritual life by circumcision and before he is otherwise cut (via subincision or gashing of the upper arm), he is shown his own clan totems, objectified in rock or wooden form, and he is told that *these* constitute his body, what he *really* is, with the implication that his physical body is of decidedly secondary significance. And this real body is generated by the sacrificial and naming acts of the Creative Period, not, as the secondary body is, by sexual relations, which, it is implied, have no sustained creative power whatsoever (Fry, 1933). Hence, again, it is unsurprising that anthropologists witnessing all-male rituals among aboriginal Australians have reported that these people are unaware of a connection between sex and generation – this despite the blatant erotic symbolism of the male pseudo-reproductive cult.

Although we do nothing quite so astonishing as subincision, there are clear parallels in western religions. Jewish males are circumcised on the eighth day after their emergence from their mothers to signify their identification with the biblical quasi-sacrifice of Isaac and perforce with all-male ritual. Christianity originally opened its ceremonial doors to women as well, as do the more liberalized forms of Judaism. But baptism was derived from the Jewish ritual bath, designed to remove the supposed decaying effects of sex from men and of menstruation and childbirth from women, i.e., to recreate an individual in unsullied form. And some modern versions of that faith – particularly in the Roman Catholic and Orthodox churches – have explicitly designated rebirth rituals in which the baptismal basin is likened to a womb and holy water to the blood of parturition, while the connection of the child to a new set of parents linked to him not through sex but through sacrifice is made by a 'father' who acts independently of women (Chock, 1974; Gudeman, 1972).

There are even approximations to ritual gender egalitarianism in aboriginal Australia. Thus Bell (1983) has made much of the fact that among the Walbiri of the Central Desert, not too-distant neighbors of the Arrernte, there are all-female secret cults; but she also tells us that these are held to be less sacred than their male equivalents, and that in order to engage in them, women need male permission, though the reverse is not the case. What is most commonly celebrated in female ritual in aboriginal Australia and elsewhere, is a girl's coming of reproductive age, but male ritual is a horse of a different color. The key enactments in the latter case are a boy's separation from his mother and his coming under the control of a male collectivity. Hence the collective nature of male pseudo-reproductive ritual. Hence too, the emphasis on

a young male's participation in the secret rituals of several clans – first his own (usually his father's as well), then those of other close kin, then those of less closely related men: indeed, a man's reputation, and this is by no means confined to aboriginal Australia, is gauged largely by the number and reputation of other men with whom he has some sort of relationship, including relationships of the 'blood brother' sort. Aboriginal Australian women, by contrast, have a much more limited sphere of sociality: most of their time is spent with their mothers, sisters, and other close kin, and when they begin to menstruate the celebration is comparably confined (Munn, 1969). This contrast seems to be widespread: indeed, Carnes (1989) has suggested a parallel in human thought between a male's progress in 'primitive' ritual life and notions of spiritual advancement in the so-called 'higher' religions.

It has been noted than an aboriginal Australian individual usually is a member of his/her father's clan. This 'patrilineal' principle is very often supplemented by another one, viz. that an individual is a member of the clan on whose territory the father had the dream experience already noted. Hence Maddock (1974) writes of 'conception clans,' i.e., units composed of individuals linked to the same territory through this sort of experience. But this is misleading, for two reasons. First, it is becoming increasingly clear that the dream experience occurs not at conception but at quickening, i.e., when the fetus shows obvious signs of movement (Scheffler, 1978). Second, as noted, affiliation via the experience is probably always supplementary to, rather than competitive with, affiliation directly through the father's membership. In fact, Myers (1986), writing of the Pintupi of Australia's Western Desert, lists no fewer than 36 principles, each apparently complementary with the others, by which individuals can become affiliated to clans. These include (1) conception (quickening?) at the associated locale; (2) conception (quickening?) at another locale created by the same Creative Being who created the first locale; (3) conception (quickening?) at another locale mythically traversed, though not created, by the Being who created the first locale; (4) subincision at the associated locale (for a male); (5) birth at the associated locale; (6) conception (quickening?) of one's father at the associated locale; (8–11) conditions two to five true for one's father; (12) conception (quickening?) of mother at the associated locale; (13–16) conditions two, three, or five being true for one's mother; (17–20) conception (quickening?) of one or another grandparent at the associated locale; (21–34) conditions two, three, five or (in the case of grandfathers) four being true; (35) residence in or near the associated locale; and (36) death of a close relative in or near the associated locale. The Pintupi case more than any other study shows that neat and established labels like 'patrilineal' and 'matrilineal' cannot be applied to totemic groups.

Then there is the supposedly invariant animal connection. Even in the classic Arrernte case, the animals are represented as beings who are partly human, and in the course of myths these beings change shape back and forth and sometimes have no animal aspect (Morton, 1987b; Spencer and Gillen, 1899). The Rock Python, as noted, is an important totem in the monsoonal north, but so are two human sisters with whom it is mythically associated (Berndt, 1951). Aboriginal people in this area had long contact with Indonesian fishermen until about a century ago. So it is not too surprising that the mast of an Indonesian ship is a totem of some of the clans (Warner, 1937; Worsely, 1955). Even when the totems have animal form, they do not figure, as they do among the Arrernte, in increase rites. What *is* remarkable is that, regardless of the form of the totem, its historicity is never admitted; rather, it is presumed always to have existed. There is good evidence that over time clans sometimes die out or split into two or more such units (Keen, 1995); and, as just noted, they adopt new totems, some but not all of which may be shared with other clans; but such historical change is not acknowledged. This primitivism, or, as one scholar has put it, 'the will to devalue time' (Eliade, 1959), is a regular feature of religious thought. Thus although we know that Jesus was an historical figure who emerged in fleshly form in what was then Roman-occupied Judaea in the first century, his advent was supposedly prefigured in Old Testament prophecy, and indeed the very first verse of the Book of John places him "In the Beginning" of things. And supposedly secular Marxist theory posits a Return to an Age of Primitive Communism.

A good example of (something like) totemism is provided by North American baseball teams. Each is associated with a city or state, and each has a nickname. Sometimes this nickname is the name of an animal, as with the Detroit Tigers and the Arizona Diamondbacks. But then there are the Los Angeles Dodgers. How on earth did this happen? Here are the facts. The Los Angeles Dodgers used to be the Brooklyn Dodgers, who did not move west until 1958. Brooklyn, however, is neither a city nor a state but one of the five boroughs that make up New York City. So the 'totemic' plan is doubly challenged. We can account for one challenge by the consideration that, until 1897, when professional baseball was already nearly three decades old, Brooklyn was a city of its own; but the other challenge – the lack of an animal name – remains. Aha! The Dodgers were once called the Robins. The name was changed because the quickest way to get to the ballpark in which they played their home games, was to cross a certain thoroughfare. This thoroughfare was circumlocuted by trolley cars, which baseball fans had to dodge to get to the game. Hence the name Trolley-dodgers, soon shortened to Dodgers. So, it might be supposed, the original plan of the National Baseball League involved only animal names. But this is not true either. The first team to join the League was called the Cincinnati Red Stockings; but the Red Stockings became the Reds (probably when the word 'stockings' became applicable exclusively to women's hosiery). The Reds became the Redlegs during the McCarthy witch hunt period, when no good American could be a Red. However, the team is now once more called the Cincinnati Reds.

There is a system here, but unlike the Bororo and aboriginal Australian clans, no attempt is made to disguise its historicity, which can readily be gleaned from the rapidly increasing library on the history of baseball. There is no notion of lineal descent, but this is also true of the clans. A fan of the Cincinnati Reds may marry another such fan but he may also marry a Los Angeles Dodger fan (though this might cause some marital strife), just as an Arrernte may marry someone of his own totem

or someone of another totem. Some animal association exists in both sets of cases, but it is limited, and, more importantly, subordinated to a more general notion which may be called *objectification*. So Lévi-Strauss needs to be revised as follows:

> objectification A:social division 1::objectification B:social division 2::objectification C:social division 3 …

Totemism is not a distinctive religion, as Freud, Durkheim, and many others (including a remarkable number of Internet 'totemites' in search of their Inner Wolf or Bear or Lion) have thought. Similarities with western religions have been noted in the course of this article. It should be added here that the Cree Indians of the Great Lakes area in Canada, like the Arrernte, have rituals to increase the supply of animals, but, unlike the Arrernte, have no clans whatsoever (Brightman, 1993; Tanner, 1979).

In researching this article I have been struck by the number of other articles – in books and in electronic form – beginning glibly with "Totemism is …." It seems as if, because there is a word out there, it must pertain to something real; and what we regard as real is just the instantiation of definitions. This, again, is reification, and it is the stuff of which religions and introductory anthropology texts are made, but it is not based on empirical inquiry. A consideration of pertinent ethnographic materials suggests, at best, only the limited set of analogies just noted. It is in such a limited sense that I have used the term 'totemism' in the course of this article, and it is the only sense which, by my lights, does not violate the ethnographic data.

Abstract

Alain Touraine's distinctive contributions to sociology include his sociological theory of action, the method of 'sociological intervention' in the study of social movements, and his critique of modernity which offers a 'post-social' approach to contemporary societies. This article explains the key stages of Touraine's work in the context of post-war social theory in France. It considers some key criticisms of his theoretical and empirical work as well as his influence as a sociologist and public intellectual.

Introduction

Alain Touraine, the French sociologist, is most renowned for three major contributions to the discipline: his sociological theory of action; the method of 'sociological intervention' in the study of social movements; and his critique of modernity which offers a 'post-social' approach to contemporary societies. The unifying theme is the sociology of the subject and social actors, which he understands in terms of the forces which are tearing apart modern experience and the actions which can help to rebuild it. Like other influential sociologists of the post-1945 generation in France, Touraine pursued his career through the elite Ecole Normale Supérieur (ENS) and the institutions of the French higher education and research system centered in Paris. In 1958 he created the Laboratoire de Sociologie Industrielle, which in l970 became the Centre d'Etude des Mouvements Sociaux of the Ecole Pratique des Hautes Etudes. He was founder in l981, and director until l993, of the Centre d'Analyse et d'Intervention Sociologiques (CADIS) of the Ecole des Hautes Etudes en Sciences Sociales (EHESS). From l960 onwards he was professor and director of studies at the EHESS, and from 1966 to 1969 was professor at the University of Paris X Nanterre.

Biography

Touraine was born in 1925 in Hermanville-sur-Mer in the department of Calvados in north-west France. He has described his family background as middle class ('bourgeois' because his father was a doctor) and his life as orderly, focused on study, and insulated from the social and political turbulence of the interwar years (Touraine, 1977: 14–16). He was educated in Paris and was strongly supported to succeed in his studies. In 1940 he obtained his baccalaureate from the Lycée Louis-le-Grand. The 'great debacle' of the German invasion and the occupation saw the first sociological stirrings in Touraine's thinking. "The society was turned upside down, its principles crumbled to dust; France, character of almost divine importance, was nothing but occupied territory" (1977: 27). But the war years were spent in more studies, the *khâgne*, in preparation for entry to the ENS. He joined the ENS as a student of history in 1945, qualifying as *agrégé* in history in 1950. The narrowness of this intellectual environment, where at this time sociology was not established as a university discipline and where there was no empirical research tradition, encouraged Touraine to interrupt his studies in 1947 to travel to Hungary and then to Yugoslavia, which was already under Soviet occupation. On his return, he spent several months working in the mines in the north of France. This first-hand experience of the living and working conditions of the world of coal mining provoked a series of sociological questions about labor, class, industrial organization, and social change which were to occupy Touraine for many years. His first sociological mentor was Georges Friedmann, the industrial sociologist, who appointed him as research assistant to study work and technological change in the Renault car factory at Billancourt. This established him as a researcher at the Centre National pour la Recherche Scientifique (CNRS), where he worked until 1958. In another important interlude, he was Rockefeller Fellow at Harvard, Columbia, and Chicago universities between 1952 and 1953. These travels exposed him to the US intellectual elite as well as to the inequalities, conflicts, and experience of social transformation among both white and black populations in Chicago. His encounters with the leading figures of American sociology including Talcott Parsons confirmed his determination to resist normative notions of 'society' and any assumption that the core of sociology is social integration, adaption, or equilibrium. An invitation to the University of Chile in 1956 was to have far-reaching consequences. It led to his marriage to Adriana Arénas (d.1990) as well as to an ongoing research interest in Latin America. As the concepts of action and social movement became central to Touraine's sociology in the late 1950s and 1960s, he was one of the most recognized figures in French sociology, which had rapidly grown into a popular field. An established scholar and public intellectual, both nationally and internationally, Touraine is a man of the left and an outspoken critic of neoliberalism. Key intellectual influences were Marxist theory (though he was never a communist, as many of his intellectual contemporaries were) and existentialism (where he draws on the antiessentialism of Sartre and his concepts of subjectivity). His thinking has some affinities with the antistructuralist position of the political philosopher Cornelius Castoriadis (1975). Touraine has continued to develop his own distinct contributions to theory and empirical analysis in a continuous, integrated fashion. These are now presented in summary form.

Touraine's Sociology

There are three recognizable phases of development in Touraine's research and publications and a fourth is still in the making. The following sections describe the main publications from each period and their significance in the development of his sociology.

1. The first phase was devoted to *sociologie du travail* or the sociology of labor (in contrast to what was usually called industrial sociology in English, which was defined more by its object of study rather than a theoretical purpose). The interest in labor reflects Touraine's direct encounters with the mining and auto manufacturing industries and the research program of the Laboratoire de Sociologie Industrielle. It is also the foundation for his early contributions to theory construction. Starting with detailed observation of the uses of automation, his research focused on the relationships, often conflictual, between the world of work, the world of organization, collective consciousness, and class movements. Broadly, the position was critical of scientific management and Taylorism but positive toward the opportunities afforded by automated processes. In *La conscience ouvrière* (1965a), Touraine characterizes the issues as a collective struggle for the control of the 'society' of industrial production (Touraine, 1977: 55). This society is not a determinate system of relations of economic production, but rather the process of genesis of values in an advanced technological milieu. In contrast to the system of craft production and its successor, mass manufacturing, the automated system represents a mutually dependent system with new forms of meaning and action, with the opportunity for a new kind of workers' consciousness. While the study was criticized for its technical flaws (see Rose, 1996) it represented an important departure from orthodox Marxist analyses of class consciousness as well as managerialist thinking. Also in this period Touraine published his first works carried out in Latin America, on the Chilean mineworkers and foundry workers.

The theoretical aspects of the argument concerning workers' consciousness were elaborated in Touraine's doctoral thesis published as *Sociologie de l'action* (The Sociology of Action) (1965b). The book builds on the historical understanding of industrial society as a system which exists as 'the child of its own creative activities,' in which labor is the paradigmatic concept (not action in the sense used by Parsons). It goes beyond interpretivism as well as functionalism and structuralism. The meaning of action is not conceptualized as the property of an individual human subject but rather as the activity of the historical subject, which is expressed in the capacities that a society has to act upon itself. It is an alternative way to describe 'society' or 'mode of production' without resorting to concepts of system, social regime, or even nation. The action approach (*actionnalisme*) is the mode of sociological analysis which aims to reconstruct the normative orientation of the action of a historical subject without reifying individuals or institutions. Workers' movements occupy the most important part of Touraine's discussion at this stage but other examples include civil disobedience campaigns and movements among ethnic minorities or religious groups. Touraine acknowledges the ambiguity between the subject defined in terms of an historical notion of labor (human–nature relations, technical divisions of labor, relations of production, and so on) and the philosophical notion of the normative orientation of conduct of the subject and its contribution to planning, programming, and controlling. However, some of these ideas become clearer when applied to the specific issue of the emerging forms of social conflict discussed in *La société post-industrielle* (1969) (The Post-Industrial Society). Despite the title, Touraine's preferred term is 'the programmed society,' which better conveys the way in which the society acts upon itself through advanced technical systems, education, and a cultural model of constant change. These are the very points at which an 'explosion of contestation' occurred in the 1960s (Touraine, 1969: 232). For Touraine, these vigorous but only partly coherent new movements (not yet capable of grasping the totality of the cultural model of the new society) represent the reconfiguration of the historical subject, 'tomorrow's social history.'

The first phase of Touraine's work in which he aimed to redefine the core concepts and tasks of sociology culminated in the book *Production de la société* (1973a) (The Self-Production of Society). Here he continues to strongly insist that sociology must reject all assumptions that try to represent society as an actor: "the social order has no metasocial warrant for its existence" (1973a: 8). He presents the alternative in terms of three central concepts:

> "*historicity*, which defines the instruments of society's self-production; the *system of historical action*, meaning that totality composed of social and cultural orientations, by means of which historicity exercises its dominion over society's functioning; and *class relations*, struggles for the control of historicity and of the system of historical action" (1973a: 13).

The first part explains and defines each of these concepts in turn. The final chapter discusses the role of sociology, while the other chapters offer detailed theoretical analysis in political sociology, social organization, and social change which prepare the ground for Touraine's later sociological practice, especially in the study of social movements. Society differs from an organism which seeks to ensure its stability by homeostasis. Its capability is not limited to adapting itself to its environment but is society's capacity to act upon itself and to modify the rules of its own functioning and self-representation. This is 'historicity.' It possesses a symbolic capacity that enables it to construct a system of *knowledge* together with technical tools which it can use to intervene in its own functioning.

The components of historicity are the model of knowledge (image of society and nature); accumulation (the economic formation of a surplus for work on work); and the cultural model (which constitutes societal recognition of the gap between historicity and functioning and includes the image of creativity). When this insistence on historicity is linked with concepts like industrial or postindustrial society, it verges on historicism but the theoretical foundations were set for the next stage of Touraine's work which had already begun with

his theoretical and practical engagement with the manifestations of social change both in France and internationally.

2. At the time of the May 1968 events in France, Touraine was professor and head of department of sociology at Nanterre where, from a leftist position, he mediated between the educational authorities, his fellow faculty, and student factions, making few friends along the way. These experiences were a laboratory for Touraine's sociology of action and he took the cultural revolt to be a new kind of struggle to take over control of social change in the programmed society, as he explained in *Le Mouvement de Mai ou le Communisme Utopique* 1968 (The May Movement: Revolt and Reform). Equally important for Touraine's thinking during the years which followed were the military coups in Latin America, including the 1973 Chilean coup which installed Pinochet as dictator (*Vie et mort du Chili populaire* 1973b). With colleagues in the Centre d'Etude des Mouvements Sociaux he developed a distinctive research program for the study of social movements, especially those he considered to be the carriers of historicity in the new type of society. With the relative decline of labor movements, the idea of 'new' social movements was becoming widely used to describe key conflicts of postindustrial society which appeared to transcend old class divisions, such as the student movement, feminism, antinuclear, and environmental movements. If the movement of labor was the central social conflict of industrial societies, it was thought that there should be a comparable central axis of conflict in the system of historical action of postindustrial societies: the struggle against political and social, not just economic, domination (*Pour la sociologie* 1974: 187–188).

A short definition of Touraine's concept of a social movement is that it is "the organized collective behaviour of an actor struggling against an adversary for the social direction of historicity in the concrete collectivity" (*La voix et le regard*: p.103). A movement is defined by the combination of three principles: identity, opposition, and totality. Without all these elements it will fall short of influencing a new cultural model of society. Actors have to define themselves as such, so identity (I) refers to the self-consciousness of social actors, their awareness of themselves as subject to domination, and capable of acting. Opposition (O) refers to conflicts between opposing sets of interests, the definition of the adversary. Totality (T) is the principle which combines these elements. It defines a common sphere of action in which the stakes of social change are recognized by both the movement and its adversary (in the case of industrial society, the model of industrialization). This IOT analysis is now widely identified with Touraine's contribution to social movement theory and its value is that it can be used to analyze the relationship between the elements of a movement (I–O, O–T, I–T) and thus explain its trajectory, impact, or self-limiting features.

While these concepts demarcate a particular approach to the study of social movements, Touraine's most distinctive contribution in this field is methodological: the development of the method of 'sociological intervention,' explained in *La voix et le regard* 1978 (The Voice and the Eye 1981) and demonstrated through a series of empirical studies including the antinuclear movement (Touraine et al., 1980) and the Occitanist movement (1981). Intervention is consistent with the theoretical definition of social movement as the struggle to reconstitute the social, not simply exert pressure on institutions or express an identity. It consists in the sociologist entering into the activities of a social movement to create controlled and experimental situations to bring to the surface the relationships, the conflicts, or the agreements of which it is made up. The role of the researchers – who have roles both as 'interpreters' and 'analysts' – is to interact with activists in meetings constituted rather like focus groups (avoiding the movement leaders who will tend to speak for the movement). The method promotes a self-analysis of the movement, to reinterpret its past, to critique its assumptions and ultimately if 'conversion' occurs, to reorient its action.

In 1981, Touraine spent a year in Poland with a French and Polish research team studying Solidarity, which was the most significant opposition movement in Eastern Europe in the late Soviet period. It was built on a trade union and working class base but in the context of the Polish party-state it developed national and democratic ambitions for the whole society as well as rights for workers. In Touraine's terms this was a 'total' social movement. At the same time, its character was defined by internal differences between two strands: the movement among workers to defend their rights and the movement for liberation of society (involving intellectuals as well as workers). In a review of this work, Martell and Stammers (in Clark and Diani, 1996: 127 ff.) commend the results of the intervention method for its detailed understanding of the self-definitions of actors in Solidarity. However, they point out that the research pays less attention to the organizational and political dynamics within the movement, or to the more shadowy aspects of populist nationalism and neoliberal thinking contained within Solidarity. As a counter to the criticism, it is clear that Touraine's studies in Latin America (e.g., on Chile in *La Parole et le Sang* 1988) and his later writings on French politics are rich in detail on such questions.

Touraine's numerous studies of movements demonstrated a problem with applying the assumption of a central conflict associated with a given system of historical action or type of society (e.g., an antitechnocratic movement to transform the programmed society). Actual social movements are an unstable combination of elements in concrete national and local settings. "Like all the elements of a modern society, social movements are both more autonomous and more fragile than in societies where overall principles of – political, social and cultural – integration existed" (Touraine in Clark and Diani, 1996: 311) Yet Touraine insists on the unity of a general definition of social movements even when the characteristic form of new social movements is fragmented rather than united around a common principle. This helps to explain why the main focus of Touraine's work shifts away from movements as such (although he has continued to publish in this area and places increasing emphasis on feminism and social transformations associated with gender, e.g., *Le monde des femmes*, 2006).

3. The beginning of the third period of Touraine's work is marked by *Le retour de l'acteur* (1984) (Return of the Actor), a collection of essays and articles offering a restatement of

his theoretical position in the light of his studies of social movements and political developments. It also responds to contemporary developments in social theory, notably the growing influence of post-structuralism and post-modernism. The key concepts from earlier work remain: he continues to demystify the illusion of social order and coherence, he insists on the capacity of society to make history (historicity) and, predicably, the actor remains the central concept. He questions and updates each of the themes. The direction of travel is toward a more extended analysis of the meaning of modernity and Touraine's diagnosis of the crisis which develops from the inherent tension between rationalization and 'subjectivation,' which he capitalizes as Reason and Subject to indicate their status as historical principles. The fullest statement of these themes is *Critique de la modernité* (1992) (Critique of Modernity). The aim of this work is to seek a new definition of modernity distinct from rationalization and secularization, which are typically seen as the all-absorbing, linear processes of the last three centuries. Touraine's vision of the transition to modern society is one of a creative, turbulent, interrupted process involving cultural fields, social actors, and forms of political action. The period from the 1960s to the 1980s was the period of crisis in the transition from industrial to programmed society when the conflict between the technocratic vision and the new movements to liberate the subject came to a head. Touraine's thesis rejects the myth of integration associated with concepts of tradition and community. Instead, from a resolutely modernist position he explores the societal conflicts that are characteristic of modernity and their associated social philosophies and cultural models.

The key theme in *Critique de la modernité* is the dissociation between means and ends, the divergence between the system and actors, instruments and meaning. The failure of dialogue between the two principles is responsible for the dictatorship of reason on the one hand and an obsession with the subject (e.g., narcissistic individualism) on the other. Cultural identity has ceased to be about community and is a matter of personal conviction without social roots. While there are some clear similarities between this distinction and other categories in contemporary social theory (system and life world in Habermas, or structure and agency in Giddens, for example), Touraine has a unique understanding of the crisis that is produced by the opposition between growing system rationalization and its opposite, the retreat into subjectivity. His credo is that "we do not belong to a society; we attempt to construct our life histories, to be the actors of our own histories by mobilizing our cultural resources to enter the world of markets and technologies" (Touraine in Clark and Diani, 1996: 300). The individual is neither a victim of the system nor an autonomous entity. But some of Touraine's critics are right when they point out that subjectivation holds more fascination for him than the workings of institutions and power (Martuccelli in Clark and Diani, 1996: 244).

Touraine gives an explicit account of how the processes of modernity are played out by specific forces of modernization at work in nationalism, commercial competition and consumption, and sexuality (1992: Chapter 3). These are the 'actors of modernization,' whose impact cannot be reduced to instrumental logic. The national state is modernity's political form and connections between modernization and nation-state formation have been central to the story of progress. But the nation relies on cultural particularity as well as universalizing, legal-rational principles. Similarly, the organization of firms for economic production for exchange and profit sees a disjunction between the rationalization of the technical system and the ends embodied in 'strategy.' The system of consumption presents a corresponding problem: previously it could be understood as the language of taste determined by social status or the actor's position in the economic system. As mass consumption develops, the correspondence between levels of status is undermined and the actor loses points of reference and becomes an "actor in search of himself" (p. 144). In relation to gender, the critique recognizes the system of gender domination and control of reproduction as well as the commercial exploitation of sexuality. The new element is the study of the conditions in which women become subjects, indeed principal actors in modern societies.

The crisis of modernity is therefore a long-developing crisis of fragmentation between the four worlds of the nation, the firm, consumption, and self (the subject able to reflect on his or her own identity) (1995: 274). Echoing Marx, Touraine says

> Human beings make their own history, but they do so through social conflicts, and on the basis of cultural choices. We have not left industrial society and we have not entered post-modernity; we are building a programmed society in which the production of symbolic goods has the central role that once devolved upon the production of material goods in industrial society. It is possible that this society may see a complete divorce between the economy and culture, just as the forces of economic or scientific development created islands of rationality in a world of tradition and community at the beginning of modernity. Yet such a rupture must be seen as pathological, and it can be analysed only as a divorce between complementary domains. The political system must establish mediations between the two.
>
> 1995: 358–359

Touraine developed the political and ethical aspects of this critique at greater length in a series of related publications including *Qu'est-ce que la démocratie?* (1994), *Pourrons-nous vivre ensemble? Egaux et différents* (1997), *Comment sortir du libéralisme?* (1998), *Un nouveau paradigme: Pour comprendre le monde aujourd'hui* (2005) which advocate a renewal of democratic politics on the basis of newly formulated demands for rights, especially cultural rights. These publications span the period when center-left and coalition parties dominated European politics, as well as the later turn to the right and the years of economic crisis. They not only defend liberal principles of equality, majority rule, and the limitation of state power but they also articulate notions of the subject, social movements, and rights that come directly from Touraine's theory of action – or more precisely, his theory of the formation of new social actors in the context of developments that threaten social decay and decomposition. While some of the content addresses specifically French manifestations of more widespread problems (e.g., *laïcité* and multiculturalism), most of it is

pertinent to any society experiencing a decline in democracy and the effects of globalization.

The global financial crisis of 2007–09 presented an opportunity for Touraine to apply his thinking to a context in which subjects or 'actors' appeared to have become very remote from the workings of the economic system. In *Après la crise* (2010) (After the Crisis) he analyzes the growing contradiction between actors and systems in what he calls the 'post-social' era and the implications that this has for the capacity for collective action by actors. The crisis is a "theatre without actors" (2010: 57) and "the crisis prevents us from transforming ourselves into subjects" (2010: 125) but he does not counsel despair. Although the processes of subjectivation have enfeebled the world of actors, the crisis has created the possibility for new, moral subjects to become cognizant of rights they have been denied and therefore to become collective actors.

4. There is no clear break between the critique of modernity and Touraine's work since 2001. The opening sentence of *La société invisible* (1997) 'Society has disappeared' already conveyed a challenge to concepts of society and the social rooted in the past. His *La fin des sociétés* (2013), 'The End of Societies,' brings together the fruits of a lifetime's work and offers a diagnosis of unregulated capitalism, the financial crisis, the Arab Spring and its aftermath, and other epochal changes. His target of criticism is all kinds of relationships between human subjects and social actors in a post-industrial, 'hypermodern' society where the logic and meanings of 'the social' are decomposing along with politics, institutions, and social movements. He deploys key concepts in a mixture of conventional and novel ways. If *Society* describes the use of resources according to a particular cultural pattern or orientation shaped by social institutions such as the welfare state (2013: 38), the 'end of society' refers to the hollowing out of key institutions, a process that is marked by the loss of capacity for integration and control of the relationship between the system and actors. *Modernization* refers to the multiple pathways (not only western) by which societies achieve a state of continuous self-transformation through the application of technical and intellectual means while *Modernity*, a singular concept, indicates the primacy of reason and universalistic criteria of judgment (2013: 413 ff.). Modernity does not refer to a particular type of society or form of social relation but rather the elevation of universal principles: "no [society] can be called modern if it refuses to place scientific reason above other modes of thinking … [or] rejects the idea of universal human rights" (2013: 420). Touraine sees the relationship between modernization and modernity as inherently complex, being manifested in the whole range of societies and political regimes as well as unfinished or interrupted projects of modernization. At the center of his thinking is the *Subject*. The subject is not the individual person (let alone a social actor) but that which gives human beings the capacity to create and to transform nature and the self. In the post-social era the subject is liberated from the constraints of religion and society which prevailed in former times. His subject is the carrier of rights that can be invoked to challenge any group or individual which denies universalist principles. The related concept of *subjectivation* refers to a convergence between individuality and universality, the highest expression of the subject (2013: 17).

The potential for subjectivation increases in the post-social context when the individual is compelled to claim the right to be an actor in his or her own world. Rights are not a natural 'given' (whether by religious mandate or natural law). They are the outcome of individual and collective historical struggles that reinforce the individual's consciousness of being a subject defined by universal rights, express the creative power of the subject, and lead to the growth of freedom. Touraine underlines the difference between this conception and the dominant view of ethics as the measure of the capacity for individuals to pursue their interests and impose their personal choices. His insistence on 'the right to have rights' (echoing Arendt) links him directly to the classical liberal democratic tradition while he simultaneously offers a distinctive post-social interpretation of ethics. Despite its apocalyptic-sounding title, 'The End of Societies' is not a pessimistic work, nor does it envisage the end of sociology or the demise of critique.

Commentary and Critiques

It is noticeable that Touraine's sociology is less well known in the English speaking world than the work of some of his contemporaries. For example, in his study of French post-war social theory, Robbins (2012) chooses five theorists including Althusser, Lyotard, and Bourdieu but not Touraine, despite the quantity and breadth of his output. His influence has been significant at various times in the sociology of work, the sociology of social movements, and in political life in France (not to mention his international profile in professional associations in sociology), but his theoretical thinking has generally been less widely applauded. It has a dialectical quality noted by Michel Crozier, his early contemporary in the CNRS, as both brilliant and stylistically opaque (in Clark and Diani, 1996: 14). That is by no means a unique difficulty in French theoretical writing and Touraine has spoken of his fear of being trapped by an ideology, including one of his own making. However, commentators have regularly drawn attention to a number of more significant difficulties in the logic and empirical substantiation of Touraine's arguments. Three can be highlighted as particularly important. First, there is the problem of the relationship between sociology and history. The early emphasis on historicity against the backdrop of the transition from industrial to postindustrial society led him to seek one central conflict in every form of society. For Alexander (in Clark and Diani, 1996: 224), this was a 'debilitating historicism' that undermined his critique of the classical approach to social movements and that prevented him from taking a more rounded view of the culture and institutions of civil society. There is a second, related, criticism which points to an empirical failure to recognize the power of institutions and incorporate them into his analysis. His sociology of action does not embrace all forms of action. Joas and Knöbl (2009: 427), for example, point out that Touraine does not examine the machinery of the state, institutions, or markets: "often, he merely characterizes them by deploying the highly imprecise term 'anti-subject.'" Similarly, Martuccelli (in Clark and Diani, 1996: 244) identifies a failure to theorize

power and the ruling class. This alleged weakness needs to be seen in context, which is Touraine's aim to provide sociology of the subject and a corrective to 'institutional sociology.' A third type of criticism is directed toward Touraine's theory of democracy, which is to all appearances like a conventional defense of liberalism. Some objections are misplaced because Touraine's writing on the subject is often polemical and linked to specific circumstances. It is more fruitful to read his political writings since the late 1990s in the light of his theoretical statement in *La fin des sociétés*, which offers an interpretation of the concept of a universal 'right to have rights as subject,' able to incorporate particularities, without the need for recourse to historical, metaphysical, or religious foundations.

For Touraine "the starting point for social science will always be a distrust of 'the social,' and it must distance itself from anything that reduces the workings of society to a technico-administrative operation" (1992: 127). In this sense, he is a critical sociologist who seeks categories that can capture the self-transforming character of social relations, avoiding determinism and invalid assumptions of social coherence. As an active public intellectual, he has been equally committed to social and political action that can serve to increase the capacity of subjects to act with freedom and solidarity as they make their own history.

Abstract

Tourism has become a tremendously important phenomenon in the contemporary world. This article deals with the sociocultural implications of tourism from an anthropological point of view. After presenting the general framework of the anthropology of tourism, the article examines various aspects of the phenomenon of tourism: the tourist, the tourist experience, the host society, 'touristic culture' or the culture produced by tourism, and sustainability in tourist development. The article concludes by suggesting the future.

The Age of Tourism

Humankind has traveled since ancient times, but the phenomenon of tourism is a new kind of travel born of modernity. The word 'tourism' began to be used only in the nineteenth century due to the development of modern transportation technology – such as the steamship and train – and to socioeconomic changes caused by the industrial revolution. Prior to these developments, travel was difficult, requiring patience and effort. In fact, the English word 'travel' is etymologically related to the French word 'travail' meaning 'labor.'

In the West in the second half of the twentieth century, the prevailing work ethic was transformed as people's desire for making life worthwhile through leisure and enjoyment became increasingly evident. The length of the working week decreased and paid holidays lengthened. As a result, tourism as a form of leisure activity became widespread in developed countries and also among the newly emerging middle classes of developing countries.

According to the United Nations World Tourism Organization (UNWTO), 980 million people traveled across their respective national borders in 2011. The figure is expected to grow to 1.6 billion in 2020. We are undeniably in the age of global human mobility. Against this background of a massive expansion in tourism, many countries, both the developed and the developing, are now pouring resources into the tourism industry, which they see as an important option for economic development. The World Tourism and Travel Council (WTTC) estimates that the total economic contribution of tourism industry in 2011 was 9% of the world gross domestic product and it concerned 8.3% of the gainfully employed people around the world. Tourism has become, thus, tremendously important in the contemporary world.

The Anthropology of Tourism

In the social sciences, however, tourism was not taken seriously as a subject for research, as we see in the personal histories of pioneer tourism researchers (Nash, 2007; Crick, 1989). Among anthropologists, this area of research made its debut quite recently. The first academic symposium on tourism was held in conjunction with the annual meeting of the American Anthropological Association in Mexico City in 1974. Up until then, there were a few pioneering efforts, but nothing systematic had been carried out. The results of the symposium were published in the book, *Hosts and Guests: The Anthropology of Tourism* (Smith, 1989). Focusing on the relationships between 'hosts' (society receiving the tourists) and 'guests' (tourists themselves), this book was the first edited volume to deal with the anthropology of tourism. In the 1980s, tourism became established as an item on the menu of anthropology in the West, both for research and teaching. Outside Western academic circles, in Japan for instance, the anthropological study of tourism was initiated in the late 1980s by Shuzo Ishimori at the National Museum of Ethnology in Osaka. The first panel on the anthropology of tourism was organized at the 1990 annual meeting of the Japanese Society of Ethnology (called the Japanese Society of Cultural Anthropology since 2004) held at the University of Tokyo.

The anthropology of tourism investigates the following three fundamental research areas. The first deals with aspects of the political economy of tourism, which include tourist policy, tourist development, the tourist industry, and power relations between guest tourists and host society. The second examines tourism as a sociocultural phenomenon. The main corpus of anthropological research focuses on this area. The third pursues the meanings of tourism and tourist experiences. The central task of these three areas of focus in the anthropological research of tourism is to investigate the sociocultural implications of tourism. In fact, in many parts of the world it has become obvious that tourism is playing a culturally dynamic role. Amidst the 'global cultural flows' (Appadurai, 1996; Greenblatt et al., 2010), social boundaries are weakening and people are enjoying the benefits of cross-cultural contact. Consequently, while expressions of traditional culture are increasingly fragmented, culture is also being reinvented, especially in the context of tourism. Therefore, MacCannell (1992) observed that 'tourism is the primary ground for the production of new cultural forms on a global basis.'

These circumstances present a challenge to the student of culture. It is impossible to treat culture in the way that it once was, as a closed system of meanings and symbols. It is also increasingly difficult to use the old-fashioned ethnographic method of recording coherent, patterned cultural systems enclosed within discrete territories and peoples, as Hannerz (1996), Gupta and Ferguson (1997), Marcus (1998), and others have discussed.

The Tourist

Smith (1989) defines a tourist in the following way: "a temporarily leisured person who voluntarily visits a place away from home for the purpose of experiencing a change." Here, 'work' is contrasted with 'leisure' and time is structured as follows: tourists are released from work, this leisure time they devote to themselves, and they return to work refreshed once more. This structure of time is very similar to that of ritual as analyzed by Leach (1961) who suggested that ritual puts a stop to profane time, and creates sacred time. The end of the ritual signifies reintegration with secular time. Building on this analogy of ritual, Graburn (1989) treats tourism as a descendant of the 'sacred journey' or some version of a pilgrimage. In fact, in Europe, Japan, and many other parts of the world, pilgrimage, which provided the model for tourism, was simply a ritual-oriented journey. Tourism, therefore, may be a form of ritual in the modern world, as Graburn suggested.

Just as rites of passage bring about a change in status or circumstances through the ritual experience, what the tourist is looking for is the experience of a change. The essence of tourism always consists of experiences that are different. As a result, a trip is a success if a change can be seen in the self. People refresh themselves by traveling: they may feel they are 'reborn' or recharged with a new lease on life.

A difference in perceptions of time may also apply to the tourist space, in what Urry (1990) has called the 'tourist gaze.' Applying Michel Foucault's concept of the 'gaze,' Urry states that the tourist experience is 'to gaze upon or view a set of different scenes, of landscapes or townscapes which are out of the ordinary.' Just like tourist time, then, tourist space is marked and 'framed' to use MacCannell's term. Tourism is, as MacCannell (1992) put it, an ideological framing of history, nature, and tradition; this framing has the power to reshape culture and nature to its own needs.

However, in terms of the recent developments in tourism, one should note that there are perceptual changes about tourist time and space. In the acceleration of contemporary global human mobility, the distinction between 'home' and 'away' sometimes blurs. For example, Bali has become 'another home' for Japanese women tourists who are married to Balinese men whom they met after repeated tours to Bali (Yamashita, 2003). Since 2002, the Malaysian government has been promoting Malaysia as a 'second home' for foreign retirees. In these examples, Smith's definition of the tourist as a temporarily leisured person who is away from home cannot be easily applied; for these lifestyle migrants/tourists, 'leisure' and 'work,' 'home' and 'away,' and 'dwelling' and 'traveling' are not necessarily opposed. Therefore, we need a new definition of tourism in accordance with the changing perception of tourist time and space (Yamashita, 2012).

Like lifestyle migrants/tourists, anthropologists too are either traveling dwellers or dwelling travelers in their ethnographic journey. Some have noted similarities between tourists and anthropologists. Crick (1995), in discussing 'the anthropologist as tourist,' suggests there is a partial overlap in identities among tourists and anthropologists, and tourists may be regarded as 'distant relatives' of anthropologists. However, based on his 'ethnographer-as-tour guide' experiences in Bali, Indonesia, Bruner (1995, 2005) observes that there are apparent disparities between touristic and ethnographic ways of viewing such events as festivals. 'Anthropologist gaze,' in their professional viewing of the world is, after all, different from 'tourist gaze.'

The Tourist Experience

There are two important theories of the tourist experience. The first is the theory developed by MacCannell (1976) that tourism itself consists of the search for 'authenticity.' This starts from Marx's observation that living in the modern world produces a state of alienation in which we cannot realize our real selves. The reason why people travel is, therefore, to escape from the real world in order to experience a different world, and to discover the 'authentic.'

On the other hand, Boorstin (1962), writing before MacCannell, observes that the authentic tourist experience is impossible in the contemporary world. Rather than being a journey in search of authenticity, travel is increasingly based on artificial images. Before setting out on a trip, tourists read the guidebook. They then go to the places written up in the guidebook, and take photographs similar to those in the guidebook. This is an experience that Boorstin has called a 'pseudo-event.' Thus, the tourist experience ends up oscillating between being a 'pursuit of authenticity' and a 'pseudo-event.' Pseudo-events, simulations and fabrications, and staged and scripted events that are a kind of counterfeit version of actual happenings have become the dominant feature of tourism space and time. However, not all tourists seek authenticity; nor are all tourist experiences pseudo-events. Cohen (1979), therefore, does not regard the tourist experience as either of these two ends. He suggests instead that there are a number of different modes of tourist experience ranging from the recreational mode in search of mere pleasure to the existential mode in search of one's real self. There are, indeed, many different types of tourism (e.g., 'recreational tourism,' 'cultural tourism,' 'ethnic tourism,' 'ecotourism,' 'heritage tourism,' and so forth), and many different types of tourists, from mass tourists to backpackers. Tourist experiences also vary depending on 'who travels, and where' (Moon, 1997).

Furthermore, today, as the boundary between 'the original' and 'the copy' is becoming increasingly blurred, the very basis of the question of whether tourism is a search for authenticity or a pseudo-event has lost its meaning. *Cannibal Tours*, a film by O'Rouke (1987), illustrates this point. The film depicts a tour to the villages on the Sepik River in Papua New Guinea. As Bruner (1989) says, the tourists already know that in New Guinea things like cannibalism no longer exist. If cannibalism were to exist, or if there were to be no air-conditioned cruiser, they would probably not have gone to New Guinea. What the tourists encounter is not the real 'primitive,' but a contrived and reconstructed primitiveness. The substance of this kind of 'postmodern tourism' is, then, the experience of a copy, fabrication, simulation or *simulacrum*, and the illusory copy becomes more important than the real thing.

Cannibal Tours also raises the critical question of how this type of tourism is based upon a neocolonial relationship between the North and the South. In fact, the majority of the world's tourists are from the 'northern' countries: 57% from Europe and 16% from North America. Eighty percent of all international travelers are nationals of just 20 countries (Survival International, 1995; quoted in Mowforth and Munt, 2003). In terms of expenditure on tourism, the world's top 10 countries on the basis of spending on tourism, in 2009 – Germany, the United States, the United Kingdom, China, France, Italy, Japan, Canada, Russia, and the Netherlands – were responsible for 47.3% of the world total (UNWTO statistics). However, one should note that this Western-dominated tourist map will be changing, as the tourist market is growing rapidly among the middle classes in developing countries in Asia. China, for example, is predicted to produce one billion international tourists by 2020.

The Host Society

The anthropology of tourism investigates the 'contact zone,' or interactions between hosts and guests. The central question had been how the development of tourism influences the culture of the host society. Much of the debate has focused especially on whether the effects of tourism are beneficial or not to the host society. In discussions about the relationship between tourism and culture, tourism was often seen in a negative light, the general tenor being that it contributes to the destruction of traditional culture. However, this line of reasoning is not necessarily correct. First of all, tourism is not the only influence on host societies. Local cultures are also transformed by other factors, including industrialization, urbanization, migration, the mass media, pollution, poverty, and civil war. Therefore, it is simplistic to consider only the 'impact' of tourism as an exogenous force, assessing its effects as either 'good' or 'bad.' What is at stake is not simply the impact of tourism on local cultures, but rather how the local cultures develop and make use of the dynamic process of tourism to redefine their own identities (Lanfant et al., 1995).

It is useful at this point to recall Clifford's distinction between two metanarratives of culture: metanarratives of homogenization and loss, on the one hand, and metanarratives of emergence and invention, on the other (Clifford, 1988). A narrative of homogenization becomes an 'entropic' narrative or one of loss, where modernization or Westernization means a loss of indigenous tradition. But such narratives that regard tourism as precipitating the disappearance of an 'innocent' tradition unaffected by modern Western civilization are often incorrect, because they presuppose the idea that cultural traditions date back to primordial times, which is seldom the case in actuality (Hobsbawm and Ranger, 1983).

Regarding the creation of culture in tourist contexts, therefore, special attention should be paid to Clifford's notion of narratives of emergence and invention. Culture in this perspective is observed as always emerging; it is not something static, but a dynamic, evolving process. An example may be taken from Bali, Indonesia. In Bali, traditional culture, and particularly the traditional dances such as the *kecak* dance, have been elaborated and refined since the 1930s under the gaze of Western artists and tourists. 'Traditional culture' reconstructed in this way not only has become 'symbolic capital' for developing tourism but also has been appropriated by the local people to assert their own identity (Yamashita, 2003).

Touristic Culture

Anthropology was conventionally concerned with the view of culture as customs enacted unconsciously. Given the discussion above, culture is rather an object of conscious manipulation within a broader social, economic, and political context. In other words, culture, in the context of tourism, is not the 'authentic culture,' but a newly created, scripted 'staged culture.' Staged culture in the tourist context, or what Picard (1996) has called 'touristic culture' from his study in Bali, such as dance performances, cultural exhibitions, or souvenir production for tourists, is usually disparaged, because it is not 'authentic.' However, in the case of Bali, the 'tourist gaze' has stimulated local creativity in the arts. What, then, is the mechanism for the emergence of touristic culture, particularly tourist art?

As an example, the Sepik carvings, the souvenirs that appeared in *Cannibal Tours*, originally were used in ritual contexts. At the end of the nineteenth century, however, they were designated 'primitive art' by Western explorers, and were seen as having objective, 'authentic' value by Western scholars. Now they have been transformed into 'touristic art' to be sold to tourists. This kind of transformation occurs in the scheme of what Clifford (1988) called the 'modern art-culture system.' The Sepik carvings have, in this way, been transformed from cultural (ritual) objects to artistic objects, and from artistic objects to tourist (commercialized) objects (see also Graburn, 1976).

These phenomena do not comprise an 'entropic narrative' of traditional cultures that are vanishing. Rather, they have the makings of new cultures emerging in the context of tourism. Tourism, then, has become a catalyst for contemporary cultural production.

Tourism and Sustainability

Sustainability became something of a buzzword from the 1980s, and particular kinds of tourism could lead to increased awareness of environmental and other problems. In 1989 in Zakopane, Poland, the theme of the first general meeting of the International Academy for the Study of Tourism was 'alternative forms of tourism' such as 'appropriate tourism,' 'responsible tourism,' and 'ecotourism' (Smith and Eadington, 1992).

Sustainable tourism can be defined as development that will benefit people today without harming the resources for future generations. Sustainable tourism seeks development that maintains a balance between the ecosystem and the society and culture concerned. According to de Kadt (1992), sustainable development involves the following traits: ecological soundness; small-scale production; recognition of needs other than those of material consumption; equal consideration

of the needs of all (including future generations); and political involvement from below. Ecotourism may be a fundamental model of sustainable tourism, though it is a challenging business.

In addition to the natural environment, culture needs sustainable developments as well. Let us take an example again from Bali, which is often regarded as a successful case of cultural tourism. Until the 1980s, Balinese tourism had been confined to the southern part of Bali, but in recent years it has spread to places in all parts of Bali. Furthermore, commercialization has accelerated. Through this process, culture has become an asset, a form of 'cultural capital,' which can now be owned, managed, and controlled by outsiders – Jakartan or otherwise. Culture is thus slipping away from Balinese hands. Cultural tourism was originally encouraged so that the Balinese could control their own culture, but that culture has begun moving beyond their control. This is the paradox that Balinese cultural tourism faces today (Yamashita, 2010).

The Future of Tourism: Toward a Reflexive Tourism

As mentioned at the beginning of this article, tourism was born out of the development of the modern society. Urry (1995) states: "Central to the idea of modernity is that of movement, that modern societies have brought about striking changes in the nature and experience of motion or travel." However, the situations observed in contemporary Bali indicates that tourism, like other institutions of modernity, stands at a crossroads in the path of what Ulrich Beck et al. (2005) have called 'reflexive modernization.'

'Reflexive modernization' refers to the creative (self-) destruction of an entire epoch, that of industrial society. Beck writes: "This new stage, in which progress can turn into self-destruction, in which one kind of modernization undercuts and changes another, is what I call the stage of reflexive modernization." 'Reflexive modernization,' then, is taken as a process by which one modernity is replaced with another.

Further, as Beck points out, the other side of the obsolescence of the modern society is the emergence of 'risk society.' Tourism also must contend with the management of risk which modern society has produced. Examining the case of Bali, Yamashita has proposed a 'reflexive tourism,' which seeks an alternative modernity in the field of tourism (Yamashita, 2010). Ecotourism and heritage tourism, for example, may be regarded as typical forms of reflexive tourism, because they attempt to manage the contemporary environmental destruction and cultural disruption from the point of view of tourism. The future of tourism should be in the direction of this reflexive vein in which we attempt to manage 'risk society.'

Abstract

The field of tourism geography is seen in terms of broad, and sometimes overlapping, concerns with the space, place, and environmental dimensions of geography. Despite broad consensus around these dominant themes, the definition of tourism geography remains problematic, because of the blurred understandings of both the temporalities and motivations of tourism and tourists. Methodologically and theoretically, there have been significant shifts over time from more empirical to more theoretical approaches, and from spatial models, to political economy and cultural perspectives.

Introduction

The field of tourism geography has mostly been seen in terms of concerns with the space, place, and environmental dimensions of tourism, reflecting a long tradition in the larger discipline of geography (Wilson, 2012). The definition of tourism geography, however, remains problematic, with debates focusing on both its temporality – where, for example, does it fit in relation to temporary migration and recreational studies – and motivations, The rise of the mobilities approach has added to these challenges in recent years, while also providing new perspectives that have enriched tourism geography (Duncan, 2012).

There have been a number of shifts in the dominant theoretical and methodological approaches in tourism geography in recent years, again reflecting broader shifts in geography and the social sciences, and this article maps out three of these. The positivist approach has largely been inductive and has involved the construction of spatial models, particularly of tourism flows, an approach that has been fortified recently by technological innovations such as GPS and GIS. The political–economy approach has drawn on capital accumulation, commodification, and regulation theories, while cultural interpretations have researched the discursive, representational, and performative realms of tourism and tourist experiences. The way in which tourism geography is increasingly engaging with other social sciences is exemplified by the work on environmental issues, especially sustainable tourism, and the role of tourism in making and remaking spaces and places. Tourism geography has, however, largely been dominated by human geographers, and the study of environmental issues, for example, has mostly been in the domain of social science, rather than a meeting ground of natural and social science – or physical and human geography.

While there is a distinctive field of tourism geography studies, with its own specialist journal, *Tourism Geographies: An International Journal of Tourism Space, Place and the Environment* (first published by Routledge in 1999), there are considerable overlaps with the interests of economic and cultural geographers, as well as mobilities researchers (Urry, 2007). These have infused tourism geography with greater theoretical content in recent years, counterbalancing a traditional emphasis on empirical and applied research. Nevertheless, this has raised concerns for some tourism geographers that their field has become a theoretical borrower, leaning heavily on cognate disciplines, rather than generating its own distinctive theoretical contributions. However, other commentators point to the creative and leading role of tourism geographers in many cutting-edge discourses on subjects such as globalization, place making, and visual representation.

Definition

A recurring issue in tourism geography has been the generic definition of tourism. Most definitions emphasize that tourism is characterized by nonpermanent moves, an intention to return home within a relatively short time period, and a travel purpose other than taking up permanent residence or employment. Two difficulties arise from this apparently simple definition. First, there is no clear conceptualization of 'permanence,' an issue that has gained in importance because of the increasing diversity of human mobility and the blurring of tourism and migration (Williams and Hall, 2002). The response of leading international tourism bodies, such as the United Nations World Tourism Organization, has been to rely on the pragmatic definition of absence from home for at least one night but for less than 12 months – a device that signally fails to engage with the overlap with noneconomic temporary migration (Bell and Ward, 2000). Second, the definition chaotically bundles together diverse motivations and practices, ranging from business tourism, to visiting friends and relations, to education to pleasure. There is considerable debate as to whether tourism should only be seen as concerned with pleasure and leisure trips. However, this approach is problematic if only because many overnight trips are multipurpose, a blurring that further obfuscates the picture for those seeking simple definitions.

Another important question relating to tourism geography is whether it constitutes a field of study, which is distinctive from tourism studies. The response to this draws, first, on the traditional concerns of geography being with space, place, and the environment (Hall and Page, 2002). And, second, it draws not so much on contentious definitions, as on the implications of overnight stays, compared to journeys from home, in terms of the potential to deepen the interactions between the destination and host areas, and their respective populations. There are three main dimensions to this. First, there are

economic implications arising from the expenditures related to the overnight stay (long distance travel, commodified accommodation unless staying with friends and relatives, meals, and other services) that can lead to significant interregional and international income transfers. Some of the spending on hospitality services necessarily is not incurred in home-based leisure and recreation, which will also have significantly less impact on interregional welfare or income transfers. Second, travel – particularly with the greater distances implied by overnight stays – potentially brings tourists and local residents from different cultures into contact with each other, generating a range of social and cultural costs and benefits (Wall and Mathieson, 2006). Third, tourism brings a distinctive dimension to the environmental impacts of human activity, resulting from the scale and intensity of travel, the polarized redistribution of human activity across space, and difficult-to-change attitudes to the associated climate change and sustainability issues – captured by the notion of 'binge flying' (Cohen et al., 2011).

Changing Perspectives in Tourism Geography

The changing theoretical and methodological approaches to tourism geography research have generally mirrored wider shifts in other social sciences and particularly within human geography. In broad terms, this has been characterized by a shift from a largely inductive positivist framework to approaches grounded in political economy, and cultural theories and or postmodernism (Hannam and Knox, 2009). Tourism geography, however, remains methodologically diverse, as is evident in the title and contents of its leading journal, *Tourism Geographies: An International Journal of Tourism Space, Place and the Environment*.

Spatial Models

Positivist approaches have mostly been inductive, but there are some notable deductive contributions. Foremost among these is a relatively neglected early paper by Christaller (1963), who is otherwise best known for his work on central place theory. This article sought to conceptualize tourism flows from 'central' to 'peripheral' locations in Europe in terms of basic principles of accessibility, and – at least indirectly – was the forerunner of an array of models concerned with the spatial interactions between areas of tourist origin and destination. More recently attention has also focused on intradestination movements, mostly empirically but with some theoretical contributions (Lew and McKercher, 2006), assisted by technological innovations that are discussed below.

Pearce (1995) proposed a fourfold typology of such models. Models of tourist travel analyze the alternative routes, which link places, and the volume and character of tourist flows along these; they are often informed by a distance decay assumption. Origin–destination models are more sophisticated, examining flows to and from a multiple set of areas, and identifying spatial hierarchies of tourist destinations. Structural models are concerned with the evolution of distinctive spatial structures in destination areas, reflecting the asymmetrical power relationships between tourists, the tourist industry, and the destination society. These relationships are epitomized by the development of resort enclaves, which are spatially, culturally, and economically weakly embedded in their local milieu. Finally, evolutionary models – reflecting geographers' time–space concerns – have examined the development of tourism spaces, especially resorts.

The most widely known evolutionary model is Butler's (1980) resort life cycle model, which contends that resorts pass through a series of stages: exploration, involvement, development, consolidation, and stagnation, culminating in a number of alternative trajectories, ranging from immediate decline to rejuvenation. The key factors shaping the evolution of individual resorts are visitor numbers, the roles of local/external entrepreneurs, competition, and the pressures on carrying capacity. The model is implicitly linear and deterministic, but does acknowledge the role of human agency in the latter stages when alternative futures are possible, depending on the responses of the tourism industry complex. Although the model is more descriptive than explanatory, its imaginative insights have influenced a generation of subsequent researchers such as Agarwal (2002) who have sought to operationalize the model in a variety of resort settings. It has also spawned a considerable debate as to the shape of the resort development curve, the determinants of change, and the criteria for identifying turning points between the different stages (Butler, 2006).

Positivist approaches to spatial analysis have been refreshed in recent years, at least in terms of methods, notably by developments in GPS tracking, assisted by the application of GIS systems for analytical purposes. Collecting detailed itinerary data for tourists, as opposed to home-destination flows, has always been a challenge for spatial analysis, and has traditionally been addressed through primary data collection, namely the use of trip diaries. Van de Knapp (1999), for example, demonstrated how GIS could be used to analyze the data captured by diaries, and to present these visually, so as to simulate dynamic systems. There were, however, still limitations in the amount of data that tourists were willing, or able, to capture in their diaries. These tended to focus only on the main nodes and some of the principal if generalized flows, and this deficiency was not remedied until the application of GPS systems, whereby the movements of individuals could be identified through the use of tracker devices (Shoval and Isaacson, 2007) using a range of technologies to monitor the spatial and temporal movement of visitors. Shoval (2012) has provided a technologically based link to the early work of Hagerstrand's (1970) concepts of space time geography. The collection of more sophisticated data has also led to new methods of data analysis using so-called sequence alignment methods (Shoval and Isaacson, 2007). These have the advantages of being low cost and precise, although there are significant challenges in managing the enormous volumes of data produced. These advances have also tended to reinforce an essentially empirical orientation in much of the work on spatial models, with theoretical advances tending to lag behind.

The Political Economy of Tourism

Since the 1970s, there has been a more critical approach to tourism geography, which initially at least, drew on the

experiences of the less-developed countries and on the political economy of development. De Kadt's (1979) *Tourism: Passport to Development?* argued for a more critical approach to understanding tourism impacts, and questioned the uncritical view of tourism as a vehicle of economic growth, but failed to offer a coherent alternative conceptual framework. Britton (1991), however, did set out such a framework, drawing on notions of capital accumulation, cultural capital, and the representation of place; the work of David Harvey, among others, was influential in his thinking. This key paper had two main legacies in terms of tourism geography research: the commodification of culture and place, and the particularities of tourism production within capitalist systems. Britton's work did inspire a more critical approach in tourism geography (see the overview in Sharpley and Telfer, 2002), although there has been relatively limited further development of a political economy framework.

One major exception to this has been the work of Ioannides and Debbage (1998), whose book sought to integrate studies of tourism production with economic geography. Their own contribution to this volume analyzed changes in tourism production in terms of a shift from Fordism to postFordism, drawing on regulation theory. Inevitably, they concluded that there are sectoral differences between, for example: airlines and tourism retailing, and those different forms of tourism production coexist at any one time. Moreover, Debbage and Ioannides (2012) have identified the 'critical turns' in tourism geography, which reflects similar shifts in main stream human geography. These cultural shifts engage with political economy to varying degrees. The application of regulation theory was subsequently extended by Shaw and Williams (2004) who demonstrated how the notions of regime of accumulation and mode of regulation can be used to analyze the interaction of production, consumption, and various forms of regulation in changing and diverse market economies. More recently, Bianchi (2009) has reasserted the importance of a political economy perspective in the face of what he sees as the limitations of the recent shift to cultural approaches in tourism geography, namely the failure to analyze the economic and political relations of power, material inequalities, working conditions, and social polarization. Another strand of research that is part of the legacy of the work of Britton and others is a concern with commodification, understood as the differentiation between use and exchange values. This is driven in part by debates around neoliberalism and privatization, although these discourses are still weakly represented in the tourism literature, despite the significant contradictions that exist around the use of public or free goods in tourism, and the scope for commodifying the tourism experience. Tourism geographers have also been concerned with the relationships between commodification and authenticity, exemplified in research on slum tourism (Frenzel and Koens, 2012), as well as the way in which host–guest relationships (Smith, 1977) have been mediated by changes in the nature of tourism.

Cultural Interpretations

Tourism geographers have a long-standing interest in the notion of place, and in how tourism behavior is both shaped by and shapes places. They have drawn extensively on the work of sociologists, such as Cohen (1984), who emphasized that all tourists are seeking some degree of novelty and difference, while at the same time wanting to retain an element of familiarity. The way in which tourists balance these differing needs was used by Cohen to construct a typology of tourists ranging from mass to more individualistic travelers, a theme that has run through much of the subsequent work on tourism and tourism places.

The representation of place is also of central importance in tourist practices. One of the most influential concepts in this respect was the notion of the tourist gaze (Urry, 1990: p. 2), which "presupposes a system of social activities and signs which locate the particular tourist practices." In terms of image, the tourist gaze is constructed through signs and signifiers in the landscape, with tourists being collectors of such signs. Tourist practices do not simply entail the purchase of specific goods and services but their practices involve the consumption of signs, which are constructed around and help to define notions of place. One of the most interesting aspects of Urry's thesis is the contention that, in the late-twentieth century, there was a change in the values held by tourists, and in the signposting of the objects to be gazed upon. The contrast between tourism as a separate sphere of social activity and the practices of every day life has greatly diminished. Tourism has become dedifferentiated or merged with other activities, and this has contributed – at least in the more developed economies – to a shift in interest from traditional seaside resorts to urban/industrial heritage sites, along with valued rural landscapes and cultures.

While Urry's seminal work, *The Tourist Gaze*, continues to have almost iconic importance in tourism, more recent postmodern interpretations have been characterized by broader concerns with how tourism is performed, represented, and experienced. There has been recognition of how tourism is not jut gazed on, but also smelled, heard, tasted, and embodied in a variety of sensory ways (Crouch, 1999). Molz (2007), for example, has explored the importance of eating familiar foods as being an encounter with otherness, emphasizing that culinary tourism is not necessarily about experiencing the other culture, but rather about displaying openness, and performing cosmopolitanism. Another important strand of research has been concerned with how tourism is represented and shaped in various literature, including travel writings (Robinson and Anderson, 2002).

Despite the call for a broader remit, some of the most significant contributions of tourism geographers have been in respect of the visual. Photographs play a particularly important role in the interchanges between tourists and guide books, tourists and local populations, and tourists' representations and narratives about their tourism experiences (Edensor, 1998). While much of the debate in this area has focused on the creation of spaces of exclusion, dependency and disempowerment, there is also evidence that tourist photography creates opportunities for empowerment through self-direction (Scarles, 2012). This also resonates with the emphasis on seeing practices as scripted and as places being made and performed by tourists, who themselves are transformed in this process: the outcomes are not deterministic, and there is room for contestation, struggle, and surprises (Crang, 2004).

Tourism Geography and the Challenges of a Changing World

Tourism geographers make an important contribution to debates about the role of tourism in a changing world. Two themes are of particular note in their work: the environment, including aspects of sustainability and climate change, and the restructuring of places or economies.

In recent decades, there has been considerable research on the environmental effects of tourism, and geographers have played a key role in this. Mathieson and Wall (1982) provided an early and enduring review of the impacts of tourism. Most research, subsequently, has involved a refinement of the measurement of these impacts, through such techniques as carrying capacity, rather than advances in conceptualization per se. Most of the research has been in wilderness or other protected areas and there has been surprisingly less work on mass tourist environments. In the 1990s tourism geography engaged enthusiastically with the notion of sustainability, and a specialist literature developed around sustainable tourism (Weaver, 2006). Tourism geographers have argued for a more holistic approach to sustainability, which recognizes the links between the economic, social, and environmental dimensions. They have also become more critical of idealistic attempts to build partnerships of stakeholders, as evidence emerges of unequal power relationships within these (Bramwell, 2011). The focus in recent years has increasingly shifted to the implications of climate change for tourism, the contribution of tourism to climate change, and how tourists respond to the environmental consequences of their air travel in particular (Becken, 2007; Cohen et al., 2011). Within this context, interest has also focused on 'sites of practice' and the way consumers' attitudes toward sustainable behavior contrast between home and holiday environments. The emphasis placed on practices and context reveal that comfortable notions of environmental responsibility and sustainable consumption in the home often conflict with the discourses of consumption reduction associated with climate change in tourism contexts (Barr et al., 2011).

Tourism geography is also engaging with economic restructuring, and this is particularly evident in urban areas. In the face of major declines in their traditional economies, many urban localities have looked to tourism as one, and often the leading, component in their regeneration strategies. Tourism has the advantages of being labor intensive, requiring relatively limited investment, and having the capacity to refashion place images so as to reposition localities in the wider map of economic opportunities. Tourism geographers have played a role in analyzing the social and spatial impacts of such strategies, while demonstrating that their success is in part contingent on place characteristics. Similar research also exists on the role of tourism in other types of place environments, including the rural and the coastal resort, as well as on mega events such as Olympic games. Such analyses often present tourism as part of the cultural industries, and emphasize its contribution to creativity, making links to both the experience economy and to the skills of the postmodern tourist.

In terms of the economic restructuring of tourism destinations, an area of greater interest concerns the consequences of globalization processes. These processes have been represented in a variety of ways but center on the nature of the connections that operate across national boundaries. Such global flows of capital and knowledge in tourism may be associated with the activities of transnational companies. In addition there are a series of key drivers that shape some resort destinations. These include the power exercised by dominant firms who control flows of knowledge and competencies in the global market. Of particular interest are those global agents of coastal resort developments in the so-called pleasure-periphery (King, 2001), which mainly refers to the tourism economies of less-developed countries of Southeast Asia, Latin America, and the Pacific, although increasingly also includes Africa. These agents wield significant economic power that often produces unequal relationships in the tourism destinations. As yet, there is only limited understanding of the role of resort developers and the associated key sources of finance via global investment companies, with such agencies providing important areas for research in the geographies of tourism.

Tourism, the Millennium Development Goals, and Gender Equality

Lucy Ferguson, Instituto Complutense de Estudios Internacionales, Universidad Complutense de Madrid, Madrid, Spain

Abstract

While institutions representing the tourism industry are keen to claim that tourism contributes to the Millennium Development Goals (MDGs), there is little evidence to suggest that this is the case. Indeed, in many ways tourism perpetuates underdevelopment and the violation of human rights. This article provides a detailed analysis of the relationship between tourism and the MDGs, with a focus on MDG3: promoting gender equality and empowering women. Tourism offers the potential to contribute to development goals including women's empowerment, but a significant restructuring of the sector would have to take place in order to achieve such goals.

Introduction

Tourism accounts for 5% of the world's Gross Domestic Product (GDP), 6–7% of global employment, and 30% of the world's export of commercial services. Tourism is the main source of foreign exchange for one-third of developing countries and half of the least developed countries. In 25 out of 49 least developed countries, tourism is a strategic priority in national development plans (UNWTO, 2011: p. 1). This article critically analyzes the role of the tourism sector in global development, using the original Millennium Development Goals (MDGs) as a framework for the analysis. While the MDGs are set to expire in 2015, they nevertheless remain the primary reference point for global development milestones at the time of writing. This article begins with an overview of debates on the relationship between tourism and development, setting out two contrasting positions. It then goes on to outline the policy context for tourism and the MDGs, focusing in particular on the United Nations World Tourism Organization (UNWTO), a UN specialized agency and the main international institution focusing on the tourism sector.

This article provides an overview of which goals are included and excluded from the current tourism agenda. It argues that three out of eight goals are to some extent included, while the remaining are predominantly excluded from debates. Although several MDGs are included in the tourism policy agenda, the extent to which the tourism sector has the capacity to address these issues is much in question. In order to explore this in more detail, this article goes on to discuss one particular goal – MDG3: promote gender equality and empower women. This detailed analysis argues that the ways in which gender issues are currently framed in tourism policy and practice limit the potential of the sector to contribute to this goal. The concluding comments offer reflections on the potential of tourism to contribute to the MDGs and, more broadly, the post-2015 development agenda.

Approaches to Tourism and Development

Claims about the link between tourism and global development range from the most optimistic – tourism is a force for good, poverty reduction and greater opportunities – to the most pessimistic – that tourism is destructive of the natural environment and promotes primarily exploitative relations between employers and employees as well as between 'hosts' and 'guests.' Early critical work on tourism and development focused on how the tourism industry often exploited colonial associations and turned to colonial power structures to promote and construct the industry in developing countries (Perez, 1974, 1975; Britton, 1982; Nash, 1989). In response, tourism studies turned its attention to 'alternative' forms of tourism, suggesting that these were more likely to overcome the exploitative dimensions of mass tourism in developing countries (Lea, 1993; Brohman, 1996; Khan, 1997).

In contemporary tourism, responsible tourism is an umbrella term for a range of approaches from both academia and civil society. Responsible tourism aims to increase the positive impact of tourism and reduce the negative consequences of tourism development. A particular strand of responsible tourism – 'propoor tourism' – has developed tools for aiming to improve livelihoods and increase well-being in tourism destinations. This approach targets the benefits of tourism more directly toward poverty reduction (Brown and Hall, 2008). Propoor tourism and responsible tourism, more broadly, are premised on the fundamental understanding that a more equal sharing of the benefits generated by tourism will lead to improvement for those living in tourism communities. This confidence in the potential of tourism to contribute to development is reflected in the discourse and policy of institutions such as UNWTO, where tourism is framed as an overwhelming force for social and economic progress, as discussed in more detail below.

In contrast, more radical critiques of tourism development take a fundamentally different standpoint. They argue that tourism tends to be primarily destructive, displacing communities and violating human rights. The campaigning organization *Tourism Concern*, for example, argues that countless numbers of poor and vulnerable people worldwide 'have their basic human rights violated as a direct result of tourism's growth, exacerbating their poverty and trapping them in a cycle of deprivation' (Tourism Concern, 2009). Research into the distribution of benefits from alternative forms of tourism suggests that there is no automatic connection between 'new tourism' and human development in tourism destinations (Mowforth and Munt, 2008). Further critiques come from

 http://dx.doi.org/10.1016/B978-0-08-097086-8.64080-1

those who see tourism as an essentially exploitative industry from both an environmental and social perspective. Rosaleen Duffy, for example, has extensively criticized the environmental impact of tourism on local ecosystems (Duffy, 2004). Such research has also demonstrated the ways in which tourism promotes the sexual exploitation of women and children (Pettman, 1997; Jeffreys, 1999). Other studies detail the exploitative working practices and poor labor conditions often involved in the tourism industry (ILO, 2001).

Two distinct approaches to tourism and development can therefore be identified. The first conceptualizes tourism as a vehicle for global development with the potential to contribute to the MDGs and other development objectives. While such an approach acknowledges the weaknesses and challenges involved, it is argued that these can be overcome with small changes in policy and practice. In contrast, in the more critical framing tourism is not considered so much a tool for development as a potential threat to the livelihoods and rights of people in developing countries. In this understanding, tourism is premised on the inequalities embedded in global development, and as an industry draws on these inequalities. Tourism and the MDGs are therefore perceived to be fundamentally incompatible. This article aims to draw together insights from both sets of literature in order to critically analyze the relationship between tourism and the MDGs. In order to do this, we now turn to an overview of how the MDGs feature in tourism policy and practice.

The MDGs in Tourism Policy and Practice

The tourism sector is best understood as a collection of industries operating at a number of different levels – public, private, and community – from national tourism boards to multinational hotel chains to small-scale local tourism enterprises. At the same time, there are a wide range of forms of tourism – mass tourism, ecotourism, adventure tourism, volunteer tourism, etc. As such, it is a challenging sector to analyze from the perspective of international development. While national tourism administrations are responsible for all aspects of the tourism sector in their country, nevertheless, the power and influence of multinational travel and tourism companies often means that such bodies have little control over tourism planning and processes. The main international institution with responsibility for tourism policy is UNWTO, a UN specialized agency based in Madrid. UNWTO is responsible for the coordination of tourism policy worldwide and 'provides leadership and support to the tourism sector in the advancement of sustainable policies and practices' (UNWTO, 2011: p. 1).

UNWTO is a good starting point for analyzing the relationship between tourism and the MDGs, as it acts as a reference point for all levels of the tourism sector – public, private, and community. Development is enshrined in the organization's mission statement, which asserts that "UNWTO is committed to the United Nations Millennium Development Goals, geared toward reducing poverty and fostering sustainable development through tourism" (UNWTO, 2011: p. 1). In the 2010 publication, entitled *Tourism and the Millennium Goals: Sustainable, Competitive, Responsible*, UNWTO outlines in detail the ways in which the tourism sector can contribute to the MDGs. These points are set out within the framework of Corporate Social Responsibility (CSR) and the UN Global Compact.

The first MDG to consider here is MDG1 – eradicate extreme poverty and hunger. A key claim made about tourism's contribution to development is the creation of direct and indirect employment (Sharpley and Telfer, 2002). In practice, most aspects of tourism work are dominated by informality, through high staff turnover, long working hours, subcontracting, 'flexible' working conditions, the prevalence of 'casual workers,' and seasonal variations in employment (ILO, 2001: 56–63). Multinational hotel chains have been criticized as setting a precedent for flexibilized, low-skill labor with little room for mobility and promotion of staff (ILO, 2001). However, in many ways this is also true of smaller organizations such as 'boutique' hotels employing between 20 and 100 staff. Likewise in small, 'family-run' enterprises those employees who make up the main body of the workforce do not tend to see much social mobility in their jobs (Sinclair, 1997a). As such, the claim that tourism can contribute to poverty reduction through employment creation should be tempered with a discussion of the nature and conditions of such employment and interrogated through a lens of decent work.

In terms of extreme poverty – or the 'poorest of the poor' – it is unclear that what impact tourism has in this area. Initiatives such as UNWTO's Sustainable Tourism – Eliminating Poverty (ST-EP) Program fund a total of 49 projects worldwide. This program promotes poverty elimination through the provision of assistance to sustainable tourism development projects targeted toward people living on less than a dollar a day. In terms of CSR, UNWTO suggests that companies consider the following actions to achieve MDG1: 'Local recruitment, local enterprise investment, local supply purchase, fair-trade, poverty awareness campaigns, in-kind funds, staff participation in humanitarian projects' (UNWTO, 2011: p. 12). As set out above, the 'propoor tourism' framework aims to ensure that the economic benefits of the tourism industry contribute to poverty reduction in local communities (see, e.g., Ashley and Roe, 2002). However, the concept of propoor tourism has not been debated in any substantive way in the tourism literature, and critics have argued that this approach does little to alleviate inequalities in local communities, therefore failing to alleviate extreme poverty for the poorest of the poor (Hall, 2007; Harrison, 2008). As such, it is difficult to substantiate the claim that tourism contributes to eradicating extreme poverty and hunger.

The second goal with most relevance to contemporary tourism policy and practice is MDG7 – ensure environmental stability. A wealth of literature debates the relationship between tourism and environmental protection/degradation. As outlined above, extensive research has questioned the capacity of tourism to ensure environmental stability. Recent research, for example, suggests that tourism is one of the least prepared industries for addressing the risks of climate change (Scott, 2011). Moreover, the paradigm of sustainable tourism has been subjected to intense scrutiny by academics and activists (see, e.g., Duffy, 2002). Nevertheless, UNWTO continues to promote tourism as a means of achieving

environmental protection. For the Rio + 20 event in June 2012, UNWTO organized a session entitled 'Tourism for a Sustainable Future,' outlining the relationship between tourism and environmental sustainability. Here it was suggested that tourism can be a driver of the green economy, and that sustainable development and tourism can be complementary if the right mechanisms are put in place. Within the framework of CSR, UNWTO suggests a number of actions tourism companies can take to promote environmental stability, such as 'compliance to advanced norms and standards (e.g., ISO 14001, Green Globe Certificate), resource efficiency, renewable energies, recycling and ecomaterials, wildlife, and ecosystem preservation actions (i.e., offsetting, monitoring, cleanups, etc.)' (See http://www.uncsd2012.org/content/documents/448unwto_cln.pdf. http://www.uncsd2012.org/index.php?page=view&nr=108&type=1000&menu=126 for more on this event). However, research has shown the extent of 'greenwashing' in the hotel sector, where tourism companies have recognized the value of the green consumer market. In response, promoting 'ecotourism' has become a way of gaining a competitive edge without any fundamental changes being made in business practices (Connell and Page, 2008). As such, any claim that tourism can contribute to MDG7 needs to be analyzed in the context of contemporary debates on climate change, corporate sustainability, and the dangers of greenwashing.

Little attention has been paid to the relationship between tourism and MDGs 2, 4, 5, 6, and 8 – both from a research and policy perspective. Indeed, it is difficult to find any reference to these issues in tourism policy and practice. As such, the only source of information on tourism and the other goals comes from UNWTO's 2010 MDGs publication. An overview of the suggestions made for each goal in this publication is provided here in order to understand how these development issues are framed in tourism discourse:

- *MDG2*: achieve universal primary education – Funding for schools, offering teachers grants, delivering school supplies and computers, in-company technical and language training, scholarships, and mentorship programs for staff and local community
- *MDG4*: Reduce child mortality – Social investment in health facilities, free medical checkups in company and community, nutrition advice and programs, free dispatch of medical equipment and staff
- *MDG5*: Improve maternal health – Free screenings and medical care, free supply of maternity-related complements, education programs, investment in research and development, funding of health facilities, child care facilities in company
- *MDG6*: Combat HIV/AIDS, malaria, and other diseases – In-company prevention training and awareness raising activities, host community education workshops (i.e., use of mosquito nets), free medical checkups, social inclusion programs
- *MDG8*: Develop a global partnership for development – Collaboration between public and private sectors, independent associations and NGOs to provide funding and assistance to host communities, enhance staff capacities, clients' well-being, and engage consumers (Adapted from UNWTO, 2010).

This summary of UNWTO's approach to the MDGs demonstrates that such issues are considered appropriate to be tackled by the tourism private sector, but not by the public sector or UNWTO. This demonstrates the limits of the CSR framework for tackling development issues. It is clear that these activities are unlikely to address the structural issues underlying underdevelopment, and their potential to contribute to the achievement of the MDGs is questionable at best.

This brief overview demonstrates that some MDGs are taken more seriously and others in tourism policy and practice. While MDGs 1 and 7 – and 3, as discussed below – are addressed to some extent, those addressing more complex development challenges are not effectively dealt with. This raises a number of questions about the capacity of tourism to contribute to the MDGs.

Tourism and MDG3: Promote Gender Equality and Empower Women

In order to explore the issues identified above in more detail, we now go on to analyze more extensively the relationship between tourism and MDG3 – promote gender equality and empower women (This analysis draws on an article in *Current Issues in Tourism* dealing with these questions (Ferguson, 2011)). In terms of policy, UNWTO has been markedly slow on the uptake with gender equality and women's empowerment compared with other UN institutions. Gender as a concept was not widely visible in the organization until 2007, when World Tourism Day was celebrated with the theme 'Tourism Opens Doors for Women.' As part of this event, a round table involving a broad range of participants was held with the express purpose of exploring the relationship between this theme and the MDGs, setting up a work agenda for the future. Following on from this, a further UNWTO Forum in Berlin in March 2008 explored the theme of Women in Tourism, leading to a Memorandum of Understanding with the United Nations Development Fund for Women, now UN Women.

Since these initial steps, a number of milestones have been reached in UNWTO's approach to gender equality and women's empowerment. In 2011, the first *Global Report on Women in Tourism* was published, detailing women's status and participation in the tourism industry in developing regions (UNWTO/UN WOMEN, 2011). A second Memorandum of Understanding was signed with UN WOMEN in 2011, committing both institutions to work together to:

Build on the findings of the Global Report to generate momentum for tourism's active contribution to equality and women's empowerment, as well as to develop a gender mainstreaming strategy for the public and private members of the tourism sector (http://www.unwomen.org/2011/11/unwto-and-un-women-commit-further-to-an-ongoing-collaboration/).

In addition, the 2012 meeting of the UNWTO Commission for Africa – the annual meeting of the ministers of tourism of African countries – was held under the theme *Responsible Tourism: Opportunities for Women and Youth*. This

seminar examined the ways in which tourism can be used to promote gender equality and women's empowerment in African tourism (http://africa.unwto.org/en/event/regional-seminar-responsible-tourism-opportunities-women-and-youth). Ongoing activities at UNWTO include the development of a Women in Tourism Empowerment Program and a gender mainstreaming strategy for national tourism administrations. In terms of the private sector and CSR framework, UNWTO's MDG publication suggests that companies support gender equality and women's empowerment through:

Scholarship programs for managerial coaching, professional mobility workshops, family support structures for working mothers (i.e., in-company child care programs, flexible hours for working mothers), technical training and craft learning for women local communities, etc. (UNWTO, 2011: p. 12).

In spite of these emerging initiatives on women's empowerment, UNWTO has not yet taken a global leadership stance on gender equality issues. Within the institution, gender currently falls within the remit of Ethics and Social Dimensions of Tourism Program, where it is just one of several areas the small team are concerned with, along with migration, human rights, nondiscrimination, and the protection of children. As such, there are limited resources with which to develop and promote a strong gender agenda. In addition, gender is largely compartmentalized into one department, leaving these issues outside the concern of the senior management and other departments. If the institution is serious about gender, sufficient resources and expertise will need to be committed in order for these policy initiatives to be effective and influential, as well as broad-based support across the senior management team.

In addition to UNWTO, some bilateral donors have demonstrated a commitment to promoting gender equality and women's empowerment through tourism. The Japan International Cooperation Agency funds a number of projects, which integrate gender and tourism development, along with other aspects such as reproductive health. Also in Honduras, Norwegian funding and expertise was directed toward a feasibility study on the potential for tourism to contribute to gender equality (World Bank, 2003). In 2010, The Spanish International Cooperation and Development Agency approved two projects directed toward gender equality and tourism development in Mali and Namibia in collaboration with the UNWTO ST-EP program. The World Bank has funded several projects with links between tourism and gender equality or women's empowerment – in countries such as Mozambique, Bolivia, Ethiopia, and Honduras. The 'Regional Development in the Copán Valley' project in Honduras included 'gender' as a key component from the outset (see Ferguson, 2010a). In each of these projects, tourism is framed as an opportunity to generate the conditions for 'marginal groups' (women, young people, and old people) to *access the opportunities* afforded by tourism development.

With the exception of the Honduras World Bank project, no research has been carried out on these tourism and gender projects, so they cannot be analyzed here. This is an issue in itself, as there is currently limited funding for gathering evidence on the impact of tourism projects on gender equality and women's empowerment. Moreover, such examples are sporadic at best, suggesting that the links between gender and tourism have not been explicitly made in bilateral development institutions. This again demonstrates a missed opportunity by UNWTO to generate a global dialog and partnership on tourism and gender. The critique of the relationship between tourism and MDG3 now proceeds in two ways. First, we draw on extensive research to analyze the ways in which tourism impacts on gender equality and women's empowerment in practice. Second, we explore the ways in which gender equality and women's empowerment are framed in the policies and projects set out above, and interrogate their potential to contribute to MDG3.

The Impact of Tourism on Gender Equality and Women's Empowerment

In spite of the assertions of UNWTO and UN Women (UNWTO/UN WOMEN, 2011), there is a wealth of evidence that demonstrates the ways in which tourism reinforces gender inequality and impedes women's empowerment. There is a clear segmentation of men's and women's work in tourism, whereby the majority of women's work is concentrated in seasonal, part time, and low paid activities, such as retail, hospitality, and cleaning (Sinclair, 1997; Chant, 1997). Employment conditions in both global hotel chains and smaller, locally owned enterprises have been extensively criticized in the tourism studies literature. However, these conditions become even starker when looked at through the lens of gender. The tourism industry is characterized by 'the seasonal nature of many of its activities and (by) important fluctuations even in normal periods.' These features of the industry create a 'generic tendency to operate on the basis of a core staff and to employ the labor needed for day-to-day operations under atypical contractual arrangements' (ILO, 2001: p. 48). This involves maintaining a large pool of temporary labor to be drawn upon in times of high demand, made up of predominantly young and/or female workers. The International Labour Office reports that women account for 46% of workers in wage employment in tourism globally. However, expanding the definition to include catering and accommodation brings the proportion of female labor up to 90%.

M. Thea Sinclair (1997) argues that work in tourism should be understood as a reflection of wider inequalities in the tourism industry, as the majority of women's work is concentrated in seasonal, part time, and low paid activities, such as retail, hospitality, and cleaning (Sinclair, 1997). Sylvia Chant (1997) offers a useful summary of the gendered nature tourism work:

> Female recruitment in formal sector enterprises catering for international tourists tends to draw heavily on male-constructed and male-biased gender stereotypes and to place women in occupations, which in many respects crystallize and intensify their subordinate positions in society, whether through their assignation to low level, behind-the-scenes domestic work as laundrywomen or chambermaids, or to jobs where their physical attributes are used to attract men or to gratify male sexual needs, as in front-line hotel, commercial and restaurant posts, and in entertainment establishments. (Chant, 1997: p. 161)

More recent research exploring the informal dimensions of tourism work, such as handicraft production for tourist consumption reveals similarly gendered dynamics. Hazel Tucker, for example, in her research on Turkey, argues that small and microbusiness development was not as beneficial for the women of Göreme (as it was for the men) (Tucker, 2007: p. 101). In many ways, therefore, the evidence would suggest that tourism employment has a detrimental effect on gender equality and women's empowerment, and indeed may exacerbate inequalities.

While tourism work tends to be highly segregated by gender, there are nevertheless cases in which tourism has challenged gender inequality in destination countries. As Chant (1997) has argued, despite the structural inequalities of women's participation in tourism production, such work has some benefits for the empowerment of women workers. Sinclair (1997a) similarly points to some of the increased benefits of work in tourism for women – for example, she argues that such work can lead to greater status in the household and consequently increased bargaining power in the household context. Tucker's longitudinal research in Turkey shows how women can craft out space within tourism and that this can in the long-term contribute to the 'undoing of shame' (Tucker, 2007: p. 101). In Belize, Gentry found that the alternative tourism sector 'is notable for allowing women to use stereotypes regarding their work to their advantage' (Gentry, 2007: p. 491). In research conducted in Central America, many women workers in the tourism industry discussed how they felt working in tourism contributed to their personal and economic empowerment. They suggested that male control over household income had been diminished by the many opportunities for women to earn money in tourism communities. Others enjoyed the interaction with people from around the world, in particular being exposed to different gender norms, such as women traveling alone or men taking primary responsibility for child care (Ferguson, 2010a).

To date, however, these limited benefits of tourism have tended not to be accompanied by wider influence in society. As argued below, there is no automatic correlation between women's economic empowerment through income-generating activities in the tourism industry and broader political and social empowerment. One of the main reasons for this is the lack of attention paid to women's unpaid labor in the domestic sphere, particularly as contributing family workers in tourism enterprises (Ferguson, 2013). Research on the impact of tourism in Central America shows how child care and parenting are being neglected in tourism communities due to the demands of employment in the tourism industry, increasing women's burden for social reproduction without any decrease in their assumed responsibility for such work (Ferguson, 2010b). As Darcie Vandegrift argues, "the benefits of more highly rewarded feminized work are dampened by the limits of a tourism economy that does not provide an infrastructure to support working mothers" (Vandegrift, 2008: p. 794). These findings are echoed in the majority of research on gender and tourism in contexts as diverse as China (Morais et al., 2005), Belize (Gentry, 2007), and Turkey (Tucker, 2007). These issues of women's unpaid work in tourism need to be addressed as a matter of priority in tourism policy. As the above analysis suggests, the relationship between tourism and MDG3 is far from straight forward.

Framing MDG3 in Tourism Policy and Discourse

While tourism work is highly stratified by gender due to the kinds of labor it requires and the ways in which such labor is to be performed, to some extent it can be argued that tourism contributes to economic and personal empowerment for women. In order to explore this tension in more detail I explore how gender is framed in tourism policy and practice, arguing that three key issues need to be addressed. First, a serious discussion of empowerment is required in tourism policy and discourse. Contemporary analyses have highlighted the problems of narrowly framing women's empowerment as economic empowerment, in line with neoliberal development policies (Kabeer, 2005; Keating et al., 2010). The problem for some feminists with the overarching interest in women's economic empowerment is that it is characterized by a lack of any discussion concerning the links between economic growth, development and macroeconomic policy changes, and the perpetuation of gender inequality (Roberts and Soederberg, 2012). As argued above, attempts to promote women's empowerment through income-generating activities in the tourism industry have not usually lead to broader social and political empowerment. The primary understanding of gender policy within development projects is that it relates to women in their roles as producers of tourism goods and services. In general, support and assistance for these productive activities is what constitutes the gender component of policy. As such, issues of gender equality are left out of the picture as equality of opportunity and participation are the primary policy objectives (Ferguson, 2011). Tourism policy would benefit from a more open and honest discussion of what kind of 'empowerment' is desirable and feasible. As the research set out above suggests, economic empowerment through tourism work does not automatically translate into a meaningful redress of power relations beyond a relative improvement in economic conditions.

The second issue for the framing of MDG3 in tourism policy and practice is the issue of unpaid work.

As set out above, a large body of evidence on social reproduction in tourism development communities demonstrates the ways in which the lack of child care provision and other social services is a fundamental stumbling block to promoting women's empowerment and gender equality through tourism. Policy makers would need to engage with debates around social reproduction in a serious and committed way in order to devise practical and sustainable solutions to this issue. This might include new ways of bringing in the private sector in order to encourage tourism enterprises to take more responsibility for the welfare of their employees, for example, by providing free or low-cost child care. Finally, it is important to acknowledge the limitations of presenting discussions on gender equality and women's empowerment only in a 'business case' framework. Extensive contemporary feminist research has argued that the attempt to combine a 'gender-friendly' approach to

poverty reduction and development while maintaining a commitment to neoliberal structural adjustment is ultimately limiting, and is unlikely to lead to gender equality outcomes (Bergeron, 2001; Perrons, 2005; Griffin, 2006). In order to be able to contribute to MDG3 in any substantive way, tourism policy and practice need to move beyond a CSR or 'business case' framework. A more open debate would allow the tourism sector to move beyond narrow, market-based conceptualizations and to present more creative and innovative ways of achieving gender equality and women's empowerment.

Conclusions

While the MDGs are taken into consideration in tourism policy and practice to some extent, it is primarily in terms of a CSR framework in which the private sector is expected to take the lead in ensuring that tourism makes a contribution to the MDGs. In terms of the largest tourism institution – UNWTO – certain MDGs are incorporated into policy and operations. MDG1 and MDG7 are dealt with by the ST-EP Program and the Sustainable Development Program respectively, and to a lesser extent MDG3 is tackle by the Ethics and Social Dimension Program. In practice, however, there are a number of tensions over the ways in which tourism interacts with global development issues such as extreme poverty and environmental sustainability, with many critics questioning the potential of tourism to address these challenges. In order to explore these contradictions, this article provided an in-depth analysis of MDG3, highlighting some of the problems involved in considering tourism as a vehicle for the MDGs.

Some evidence suggests that tourism has the potential to contribute to MDG3, but policy makers need to take a broad range of issues into account if they are serious about promoting gender equality and women's empowerment through tourism development. This article argues that much more needs to be done before a solid link between tourism and the MDGs can be established. It is also important to bear in mind and critically examine the ways in which tourism is harmful to global development, in environmental, social, and economic terms. These points have been elaborated here in the analysis of MDG3. While some potential benefits to gender equality and women's empowerment from tourism can be identified, the current policy framework and operations of the tourism sector are overwhelmingly in favor of reinforcing gender inequality and preventing more lasting forms of women's empowerment. The year 2015 offers a milestone for reframing commitments to global development. In order to meet their obligations, the tourism public and private sectors need to find ways to engage more seriously with international commitments, or will find themselves increasingly isolated from human progress and global development.

Trade and Exchange, Archaeology of

Glenn R Summerhayes, University of Otago, Dunedin, New Zealand

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Studies into the archaeology of trade and exchange have surged over the last few years, mostly as a result of technological innovations providing easier access to the appropriate technology. This has unfortunately not kept pace with advances in theoretical developments into the role trade and exchange plays in understanding past societies. This article will provide an overview into the prominent role that trade and exchange has played for archaeologists, and where that role may proceed in the future.

The term 'trade' can invoke images of professionals making profits in marketplaces, while 'exchange' implies the reciprocity of goods, such as food, between nonkin, or the movement of valuables within a social group itself. In this article trade and exchange will be treated equally and defined as the movement of materials or goods between individuals, social groups, or organizations. Ancient trade and exchange are often associated with rare and exotic valuable materials known to have restricted distributions, such as lapis lazuli, ostrich egg shell (Africa), amber, spondylus shell, jade, obsidian, copper, and other precious material items. Yet most past trade and exchange would have involved materials or goods used for daily existence, such as food. These, however, would be rarely seen in the archaeological record, being perishable. Thus the archaeology of trade and exchange deals mostly in those resilient artifacts hardy enough to be left in the archaeological record, such as obsidian, stone, pottery, or jade. Even then, these goods are residues "resulting from a succession of repeated exchange transactions" (Kirch, 1997: p. 228). How and why an archaeologist identifies prehistoric trade and exchange is the subject of this article.

The Development of Trade and Exchange in Archaeology

Since the 1980s there has been an upsurge in studies on the archaeology of trade and exchange. The reasons for this are twofold. First, advances in science and technology have allowed for, and made easily available, the sourcing and characterization of many materials. This provides evidence for the physical identification of their movement. Second, archaeologists began to see the usefulness in using trade and exchange in modeling the distribution of materials over space, and in explaining changes in societies over time.

Technological Developments

Developments in technology since the 1960s have led to an upsurge in chemical 'sourcing' or characterization studies. Yet the identification of traded archaeological material is not a recent phenomenon. Perhaps the most famous early study was by Anna Shepard, who in the 1930s and 1940s postulated the exchange of pottery over wide areas of the Southwest USA by analyzing mineral inclusions in thin sections to pinpoint the origins of the minerals (Shepard, 1965). Chemical techniques to identify the elemental composition of archaeological materials as a means of characterization are also not new. Neutron activation analysis (NAA) was applied on coins from the Louvre in 1952, while in 1957 oriental ceramics were analyzed using nondestructive methods of X-ray fluorescence spectrometry (XRF) and X-ray diffraction (XRD) analysis (Young and Whitmore, 1957). However, access to these techniques was restricted and costly.

A major advance in the chemical analysis of archaeological material came from the initiative of Dr R. Oppenheimer. On 8 March 1956, he assembled a group of archaeologists and chemists at the Institute of Advanced Studies, Princeton, to discuss the possibility of applying methods of nuclear research to the study of archaeology (Sayre and Dodson, 1957). As a result of this meeting, work was undertaken at two laboratories – the Brookhaven National Laboratory in the USA and the Research Laboratory for Archaeology and the History of Art at Oxford, UK. Techniques used included NAA and spectrographic methods. These early studies were reasonably successful, being able to separate pottery wares from Asia Minor, Greece, and Italy, and different factories of Samian ware. These studies laid the foundations for chemical analyses for the next three decades, in which thousands of analyses using varying techniques were carried out on many types of object including pottery, stone (obsidian, marble, chert, volcanic rocks), amber, and metals including coins. Apart from NAA, XRF, XRD, and spectrographic methods, techniques currently in use include proton induced X-ray emission and proton induced gamma ray emission, inductively coupled plasma emission spectrometry, lead isotope analysis, and electron microscopy, to mention a few. Major changes in the instrumentation of these techniques since the 1970s have meant that more elements can be analyzed with a higher precision. See Harbottle (1982) for a list of materials that can be characterized.

The choice of technique depends on availability to the archaeologist and cost. Over the last 5 years there has been a marked proliferation in sourcing studies directly as a result of easier access by archaeologists to new hand held portable X-ray fluorescence spectrometry (PXRF) machines. Such machines are affordable for anthropology departments, proving popular among archaeologists. Testimony to this is seen is in sessions

devoted to PXRF in major international conferences (see Shackley, 2010a,b).

Theoretical Developments

The importance of trade and exchange in archaeology is the result of a reorientation in the ways archaeologists have perceived trade/exchange operating in the past. The realization that migrationist/invasion models could not adequately explain the distribution of material across the landscape, nor change in societies over time, led archaeologists to look at other mechanisms. Inspired by the works of economic anthropologists such as Polanyi (1957), who defined three types of trade and exchange (reciprocity, redistribution, and market exchange), and anthropologists such as Malinowski (1922), who studied trade and exchange in a Melanesian society, archaeologists realized that trade and exchange were embedded within the social and economic structures of society. By studying trade and exchange, the intention was to reconstruct the economies and organizations of past societies and their changes over time. The access to and control over prestige goods through trade and exchange were seen as prime movers for change leading to ranked societies.

A major proponent for the study of ancient trade and exchange was Colin Renfrew. In a classic paper on trade and culture process in European prehistory, Renfrew (1969) argued that trade was a causal factor for cultural change leading to the beginning of urbanization in the Aegean. An increase in trade with new wealth, craft specialization, and communication, led to change from a 'village subsistence economy into an urban society'. This was a marked shift away from inferring invasions or diffusion from a 'higher culture' to account for the Aegean Early Bronze Age. See Rathje (1971) for a similar case study involving the Maya.

Current Theory and Research

From these earlier studies a number of influential edited volumes on the archaeology of trade and exchange appeared: Sabloff and Lamberg-Karlovsky (1975), Ericson and Earle (1977), Earle and Ericson (1982), Renfrew and Shennan (1982), and Renfrew and Cherry (1986). These proceedings covered an eclectic array of topics from the Old World and New World, and provided the benchmark for trade and exchange studies for the next decade. These studies were important not only in identifying the movement of materials in the past, but also in cementing links with the chemists, geologists, or physicists who undertook the physicochemical analyses which demonstrated that trade and exchange took place. These studies are also important in initiating innovative research into the archaeology of trade and exchange, such as correlating the distribution of materials with modes of exchange and types of social organization, or exploring the relationship between trade and exchange with production and consumption patterns. These innovations will be discussed below.

Within this research a distinction has been made between two schools of thought about the way in which trade and exchange should be modeled: formalist and substantivist. The formalist approach works within the paradigm of market economics. Here, all exchange transactions can be viewed by economic rationalism, based on cost efficiency. Falloff models presented in Section Distribution Patterns are based on cost efficiencies. The substantivist school, on the other hand, views exchange as being embedded in social and economic processes. This approach allows an investigation into social groups, and social change. In reality, archaeologists draw from both approaches to model ancient trade and exchange.

Research mostly followed the following steps:

1. identifying that exchange/trade took place;
2. modeling the distribution patterns of the exchanged/traded material.

Identifying What Is Moving and What Is Not

Trade or exchange *must be demonstrated* rather than assumed. Archaeologists often view stylistic similarities over large distances as a consequence of exchange. Stylistic similarities in pottery, for instance, have been equated with the trade or exchange of pots from one or a restricted number of centers. Yet, in many instances this is not the case. One pottery tradition, Lapita, for instance, is spread from Papua New Guinea to Tonga, a distance of over 4000 km. It is stylistically homogeneous, having a suite of shared decorated motifs made by a dentate stamping technique. Before the 1970s it was thought that this pottery was made in one or a handful of manufacturing centers and then exchanged to other communities, thus accounting for its spread within Melanesia. Yet, after extensive petrographic and chemical analysis, it was established that with the exception of a couple of assemblages, most Lapita pottery is locally made. It was people and ideas that were exchanged, not the pots. Thus, if local production of an object is demonstrated then models other than the trade/exchange of the object must be developed to account for stylistic similarity.

Identifying the source of an object and studying the context of production is not easy. The use of a 'resource zone concept of source' is useful here in defining a geographical region from which the object was produced (Clark et al., 1992). For instance, the exact spot where the firing of a pot took place, or where obsidian was extracted, is not crucial here, only whether the pottery is of local origin or not, or whether the obsidian originated from a defined area. Attributing an object to a general regional zone (or procurement zone) is often more important than trying to identify a precise spot for manufacture.

The aim of many physicochemical analyses is to discern the geographical origin of the object under study. Ideally, the sources of material with restricted distribution could be characterized and 'fingerprinted' chemically or petrographically. Obsidian, for instance, is chemically homogeneous, and its sources can be chemically fingerprinted. Obsidian found in archaeological contexts can be analyzed and related back to the source. Identifying the potential source areas of a material requires an intensive search within a known region. For instance, in a recent study on obsidian exchange within the western Pacific over a 20 000-year time span, archaeologists have concentrated on the source areas within West New Britain,

Papua New Guinea. Over a number of years, obsidian flows were mapped and samples taken for characterization, with the result that a finer discrimination of sources was possible with five source localities chemically defined (Summerhayes et al., 1998). By analyzing obsidian found in archaeological sites (some up to 3700 km distant), it was possible not only to trace obsidian to its source localities, but also to define changes in the selection of different sources over time. For an overview of archaeological approaches to obsidian studies, see Shackley (1998).

Pottery, on the other hand, is more difficult to characterize or fingerprint (*see* Ceramics in Archaeology). Often archaeologists use what is called a 'criterion of relative abundance', which infers that most pottery from a production center is to be found locally. Yet if pottery was produced for exchange only, then little would be found locally, thus limiting the application of this concept. The 'criterion of relative abundance' is useful, however, when used with a physicochemical analysis for provenance studies; that is, relating the pottery under study back to its raw materials: nonplastic inclusions (minerals, sands, etc.) and clay. Mineral inclusions found within pottery can be related to local geology and both river and beach sands. Clays, on the other hand, vary greatly in respect of the underlying geology, and a study of the elemental composition of pottery may give a clue to its origin. The chemical analysis of clay is complex. Bishop et al. (1982) note that clay minerals not only depend on their parent material, but are also affected by weathering or hydrothermal activity, climate, and geomorphology. They state that, "even if a region is considered to be homogeneous in its gross geologic characteristics, significant mineralogical and chemical differences may be discerned between clay deposits" (Bishop et al., 1982).

In any provenance study of archaeological objects a few words of caution from Garman Harbottle, a nuclear physicist, should best be heeded:

> archaeologists love the term sourcing, with its upbeat, positive thrust—that you analyze or examine an artifact and, by comparison with the material of known origin, 'source' it. In point of fact, with very few exceptions, you cannot unequivocally source anything. What you can do is characterize the object, or better, groups of similar objects found in a site or archaeological zone by mineralogical, thermoluminescent, density, hardness, chemical and other tests, and also characterize the equivalent source materials, if they are available, and look for the similarities to generate attributions. A careful job of chemical characterization, plus a little numerical taxonomy and some auxiliary archaeological and/or stylistic information, will often do something as useful: It will produce groupings of artifacts that make archaeological sense. This, rather than absolute proof of origin, will often necessarily be the goal.
>
> (Harbottle, 1982)

For an overview of archaeological approaches to pottery characterization studies, see Neff (1992).

Distribution Patterns

Archaeologists analyze the distribution of an object from its source or production area to its consumption site in order to model the type of trade/exchange that took place. In some instances the nature of the society participating in the trade/exchange system is inferred, such as egalitarian vs chiefly, or nonhierarchical vs hierarchical.

Popular among archaeologists is the use of falloff curves and modes of trade/exchange. By plotting the frequency of an item against distance from its source (falloff curve), Renfrew (1975) observed different distribution patterns which he attempted to relate to modes of exchange or access. Some of these modes included reciprocity, down-the-line, and central-place exchange.

How were falloff curves and modes of exchange related? Down-the-line exchange and reciprocity led to an exponential falloff in abundance away from the source or production center. The term 'law of monotonic decrement' was coined to account for this falloff in the frequency of an item away from the source (Renfrew, 1977). Attempts were also made to define an object's value by the slope of the curve. A small slope equates with high-value goods, such as spondylus shells in Europe, Maya jade, and Oaxaca iron ore mirrors. These modes were equated with an egalitarian society (semisedentary agriculturalists and hunter-gatherers; nonranked; nonhierarchical).

Central-place exchange, on the other hand, was seen as directional (no exponential linear falloff), should lead to multinodal falloff curves, and is indicative of redistribution. Central place relates to the movement of goods toward one place or center, from which they are then distributed. Redistribution has been related to complex chiefly societies (hierarchical, ranked, and/or stratified societies). Examples of such societies given by archaeologists include early states such as the Maya, Egypt, the Near East, or chiefdoms such as Hawaii.

Although problems occur with equifinality – that is, different modes of exchange produce similar distributions – this approach is important as it relates the measurement of archaeological material away from the source to trade and exchange modes and the structures of societies.

Future Directions

Approaches to the archaeology of trade and exchange will continue to change on three fronts. First, change need to occur in tune with developments in archaeological theory. As archaeologists will be asking different questions about the roles of trade and exchange and society, changes in approaches and methodologies will take place. Second, at the same time, it is reasonable to expect advances in characterizing techniques, making them yet more accessible and cheaper to use. Unfortunately, over the last two decades theoretical developments have lagged behind advances and accessibility of characterizing techniques (see Dillian and White, 2010). Lastly, archaeologists will consolidate knowledge on the sources and distribution of a variety of goods, giving a more complete perspective on the roles of trade and exchange within a society. As an example, attention is drawn to the Pacific, where the production and distribution of a number of materials, such as pottery, obsidian, chert, volcanic adzes, and shell artifacts, are used to show that each class of material has different production and distribution patterns. If any class of artifact were taken by itself, a 'myopic' view would be seen of the roles of trade and exchange within societies. Only by comparing the production

and distribution patterns of the complete range of material available can a proper picture of trade and exchange be given.

Trade Policy

Abstract

The notion of trade policy is a transdisciplinary object that has received considerable attention among economists, political scientists, international relations scholars, and sociologists seeking to understand its origins, nature, and outcomes. Its conceptualization has changed according to theoretical developments in each of its nurturing disciplines – the rise of neo-institutionalism and international political economy being only two of the main subfields contributing to enrich theories of trade policy. At the empirical level, the very definition of trade policy has always been contingent upon the history of the world economy. Thus, the changing nature and ever-greater significance of international trade over the past 50 years has renewed controversies surrounding the economic, social, and environmental ramifications of trade policy, and more broadly surrounding the evolving relationship between markets and states under the new constraints of globalization.

What is Trade Policy?

At its core, trade policy consists of managing the international exchanges of goods and services between national and regional economies. In the Westphalian era, this realm of public policy has traditionally been the prerogative of national governments, although the behavior of private actors has shaped international trade flows from the monopoly of the East India Company to Apple's global supply chains. The conduct of trade policy falls into two main categories: (1) the regulation of imports and (2) the management of exports, which itself is divided into export promotion and export controls. The growing significance of international trade – from 22% of world GDP in the early 1970s to more than 50% in 2012 – and the intensification of economic competition in the second half of the twentieth century prompted decision makers to develop an ever-wider array of policy tools to manage the circulation of goods and services.

Long confined to tariff duties and import quotas, trade policy has mutated into more sophisticated forms of import restrictions designed to protect domestic interests threatened by foreign competition, among which are rules of origins, sanitary and phytosanitary standards, and other technical barriers to trade. Conversely, national governments have resorted to a growing range of measures aimed at supporting both small and large exporting companies, whether through preferential loans, insurance programs, technical assistance, or trade missions. Finally, export controls remain an integral part of trade policy, although they have been generally subordinate to security interests (economic sanctions, arms controls).

Trade policy reflects a country's openness to, or isolation from, the rest of the world and is, therefore, implemented through regional or multilateral trade agreements. Multilateral agreements have been negotiated under the aegis of the General Agreement on Trade and Tariffs (GATT) since 1947, before it was replaced by the World Trade Organization (WTO) in 1995. Today, the WTO continues to promote trade liberalization (under the nondiscriminatory principle of the 'Most Favored Nation') and has played an important role in settling trade conflicts among its 150 members, thanks to its dispute settlement body.

Unlike multilateral agreements, regional accords – whether bilateral or plurilateral – are by definition preferential trade agreements (PTAs) insofar as they grant concessions to specific trading partners. PTAs have proliferated over the past 20 years as countries compete for foreign markets and/or favor regional integration over the more competitive route of multilateralism. In 2014, the WTO recorded no fewer than 583 notifications of regional trade agreements throughout the world. Trade policymakers can resort to three types of PTAs according to the degree of economic integration that they seek. Partial scope agreements such as the European Steel and Coal Community (1951) or the US–Canada Auto Pact (1965) are conducted on a sectoral basis and are often preliminary to greater economic cooperation. Free trade areas like the North American Free Trade Agreement (NAFTA) aim to dismantle trade barriers among a set of economic partners while leaving them free to pursue independent policies with nonmembers. In contrast, customs unions like the European Union imply not only trade liberalization within a certain geographic zone but also impose common external tariffs to its members.

The growing complexity of both regional and multilateral agreements reflects the above-mentioned diversification of trade policy tools. At the multilateral level, trade negotiators began to focus on 'nontariff barriers' during the Tokyo Round (1973–79). Since then, the GATT/WTO's agenda has embraced issues that go far beyond trade, such as intellectual property rights, investment, procurement, or regulatory standards (Maskus, 2000; Muzaka, 2009; Weiss, 2006). The so-called 'behind-the-border' rules have raised sensitive questions about national sovereignty and, as a result, involved an ever-greater number of trade policy stakeholders. This has made the design of trade policy increasingly complex.

Trade Policy Formation

The study of trade policy formation can be classified into four categories, each of which has its own subdivisions and variations: system-centered, society-centered, and state-centered approaches, as well as 'two-level' or 'multilevel' games. These interpretations should not be conceived as mutually exclusive

but as the different pieces of the trade policy puzzle, a complex process at the intersection of the domestic and international sphere. 'Two-level games' are particularly well equipped to depict the complexity of trade policy models insofar as they incorporate multiple variables at each level of analysis: the role of societal forces, decision makers, and institutional structures in the domestic sphere; and state actors, intergovernmental organizations, and transnational advocacy networks in the international sphere.

Structural Theories of Trade Policy

Hegemonic Stability Theory

System-centered theories of trade policy are primarily concerned with the international level of analysis. They focus on the relation between the world's distribution of power and the structure of international trade. This type of literature can be subdivided into two principal schools of thoughts: hegemonic stability theory and (neo)Marxian models.

Kindleberger's *World in Depression* (1973) is commonly viewed as the earliest formulation of hegemonic stability theory. In his study of the interwar period, Kindleberger identified Britain's inability and America's reluctance to stabilize the international economic system as the main causes of the Great Depression. Two years later, amid fears about the declining US power, Gilpin (1975) drew the lessons from Kindleberger's seminal contribution to predict that America's increasingly contested hegemony would lead to a renewal of mercantilist policies. Krasner (1976) reformulated these empirical studies in a coherent framework that would later be called hegemonic stability theory. Krasner's systemic theory of trade policy can be summarized as follows: "a hegemonic distribution of power is likely to result in an open trading structure" (Krasner, 1976). His rationale rests upon the idea that trade openness, while raising national economic income, tends to generate social dislocations as labor shifts from one sector to another. Consequently, only a large and dynamic economy, like Britain in the nineteenth century or the United States after World War II, can bear the brunt of promoting trade liberalization.

In contrast with Gilpin and Krasner's realist perspectives, Keohane renewed with Kindleberger's 'benevolent' version of hegemonic stability theory to stress the correlation between the 'leadership lag' of the 1970s and changes in international economic regimes, namely in the oil, monetary, and trade areas (Keohane, 1980; Keohane and Nye, 1977). In a reformulation of his argument, Keohane (1984) argued that cooperation can in fact persist in a nonhegemonic international system under the tutelage of international regimes. His emphasis on the 'independent life' of regimes distinguishes Keohane from Gilpin, who has continued to argue that the absence of a hegemon renders cooperation exceptionally difficult (Gilpin, 2001).

(Neo)Marxian Approaches to Trade Policy

The first prominent authors to apply Marxian theories to the international trade system were Lenin and his contemporaries. Along with the fellow Marxists Bukharin, Hilderling, and Luxemburg, Lenin interpreted imperialism as a new era dominated by *financial* capital. In this new phase of capitalism, developed countries occupied a monopolistic position and struggled for the control of foreign markets and industries. Their foreign economic policies served the interests of financial capital and were by definition the result of "the struggle of the Great Powers for the economic and political division of the world" – (Lenin, 1939). What was idiosyncratic of this period was the fact that Marxists like Lenin and Kautsky associated imperialism with mercantilist trade policies (Etherington, 1982), eventhough Rosa Luxemburg stressed the inherent contradictions between the expansionist proclivities of financial capital and the nationalist scope of protective tariffs (1968).

Conversely, the next wave of Marxian interpretations of trade policy emerged during an era dominated by trade-liberalizing policies. In the late 1960s to early 1970s, *dependencia* theorists interpreted foreign penetration in the political economies of Latin America as a source of underdevelopment. For *dependentistas*, as well as world system theorist Wallerstein, the development of capitalism divided the world economy into metropolitan centers and peripheral satellites, the former expropriating the latter's economic surplus (Chilcote, 1974; Frank, 1967, 1969; Wallerstein, 1979). Like Leninism, this form of neo-Marxism interpreted trade policy as the result of structural economic forces. As Frank wrote, "trade relations are based on monopolistic control of the market" (1970: p. 231). Within this framework, capital interests drove trade policy.

Society-Centered Theories of Trade Policy

While system-centered theories focus on the international level of analysis, society-centered or 'market' perspectives on trade policy are concerned with domestic politics. Within this framework, the policy process is the result of a struggle for influence among various interest groups, a political competition arbitrated by decision makers (Ikenberry et al., 1988). In political science, this theoretical model borrows from the American pluralist tradition and has dominated analyses on the US trade politics since Schattschneider's seminal study of the Smoot–Hawley Tariff Act of 1930 (Schattschneider, 1935; Gourevitch, 1977; Baldwin, 1985).

In the sphere of economics, theories of trade policy have developed along two standard economic paradigms: the factor model and the sector model. Based on the Stolper–Samuelson theorem, the first claims that trade will reward abundant factors (e.g., capital in the United States or labor in China), but punish or reduce the income of scarce factors (American workers or Chinese capital-owners), leading eventually to 'factor price equalization,' i.e., the convergence of factor costs (Oatley, 2006: pp 70–74). Under this assumption (also referred to as the Hecksher–Ohlin model), trade policy is driven by the competition between mobile factors of production. From these principles of neo-classical economic theory, Rogowski (1989) derived political implications: scarce factors will likely lobby for protectionism, while abundant factors will pressure the state for increased openness. 'Losers' from trade liberalization will experience declining political leverage, while economic winners will become increasingly powerful.

The second and dominant society-centered paradigm rejects the mobility of production factors and the monolithic vision of class interests upon which the factor model is based, pointing not only to the problematic conversion of low-skilled workers into high-skilled technicians, but also to the lack of

fungibility of capital from one sector (e.g., mining industry) to another (e.g., biotechnology). Instead, the Ricardo–Viner model holds factors as 'specific' to industries and focuses on the conflict of interests between sectors, and more precisely on the competition between import-competing industries and export-oriented companies (Schattschneider, 1935; Bauer et al., 1972; Baldwin, 1985; Magee and Young, 1987; Alt et al., 1996). While these two economic theories are generally considered to be mutually exclusive, Hiscox (2001, 2002) has sought to bridge the gap between factor and sector models. He argues that coalition patterns depend on interindustry factor mobility. Thus, broad class-based coalitions are more likely where factor mobility is high, while narrow industry-based coalitions are more common where mobility is low.

While conventional society-centered interpretations of trade policy provide useful insights into the domestic dynamics of trade policy, they tend to neglect or downplay the importance of two major developments in the international political economy. First, the often missing items in societal trade models are the transformative effects that the geographic mobility of capital has had on trade politics over the past three decades. Indeed, since the 1970s, multinational corporations have developed complex global supply chains leading to a dramatic expansion of intrafirm trade. The rapid liberalization of international trade and investment flows contrasts with the enduring immobility of labor. This asymmetry has generated intrasectoral class conflicts that conventional sector-specific models can hardly explain. On the one hand, multinational corporations can benefit from the cost reductions resulting from outsourcing and are, therefore, prone to support laws that liberalize trade and investment flows. On the other hand, domestic workers are the first victims of offshoring and will logically oppose the very same trade agreements – as witnessed by the protectionist retrenchment of American labor since the 1970s (Helleiner, 1977; Moody, 1997; Darves and Dreiling, 2002). The growing class cleavages of American trade politics have been particularly visible during the recent debates on NAFTA, which, for instance, pitted autoworkers against their employers (Chase, 2003; Cox, 1995).

A second lacuna of both factor- and sector-based models is related to another feature of contemporary trade politics that cannot be captured by class-based analyses: the expanding scope of trade policy beyond tariff barriers. The growing social and environmental ramifications of trade agreements logically triggered the political mobilization of new trade policy stakeholders among who are environmentalists, consumer advocates, or human rights groups. From the NAFTA debates to the Seattle protests of 1999, nongovernmental organizations in the United States and elsewhere have invited themselves to the negotiating table (Hinojosa-Ojeda, 2002; Mayer, 1998; Vogel, 1997; Destler and Balint, 1999; Esty, 1998). They have struggled to broaden the terms of trade debates in a policy sphere long reserved to trade associations. Some scholars have focused on the challenges and opportunities inherent to integrating trade policy and environmental regulation (Gallagher, 2004; Fickling and Schott, 2011). Others have examined the rising prominence of labor standards in the trade policy sphere and pondered whether globalization deters or encourages the enforcement of labor and/or human rights (Elliott and Freeman, 2003; Flanagan, 2006).

Globalization scholars are often better equipped to study the dynamics of these new trade-related debates than conventional trade economists. The latter tend to reduce trade policy outcomes to either free trade or protectionism, thereby leaving aside important moral questions on the social terms under which international trade takes place.

Finally, and despite their dominance in the field, society-centered studies of trade policy have been criticized for their disregard for the role of decision makers and institutions. In particular, the market-based approaches described above often reduce the policymaker to "an auctioneer in a product market" (Magee and Young, 1987), a lacuna that has been challenged by neo-institutionalist scholars.

State-Centered Approaches

Over the past two decades, political science has departed from pluralistic, economics-based models of policymaking to 'bring the state back in' and (re)emphasize the conditional autonomy of government on the hand, and the 'policy legacies' of institutions on the other (Evans et al., 1985; March and Olsen, 1998; Immergut, 1998). This renewed interest in institutional forces gave rise to state-centered approaches to trade policy, which fall into two categories: 'state-as-an-actor' theories, which highlight the independence of decision makers, and institutionalist models, which stress the impact of domestic structures.

Within the former literature, the emphasis is on how governments shape trade policy to defend their national interest, of which international competitiveness is a crucial component. Under this category of argument falls the perennial 'infant-industry' argument according to which government must shield its emerging domestic industries from foreign competition until they become fully competitive. This argument can be traced back as far as 1645 (Irwin, 1996), but was most famously enunciated by Alexander Hamilton (1791), who called for the adoption of tariff duties to protect its nascent manufactures of America. This challenge to the free trade orthodoxy of classical economists like Adam Smith and David Ricardo reemerged in the 1980s under the banner of strategic trade theory. Often associated with the work of Brander and Spencer (1983) and Krugman (1986), strategic trade theory took stock of the imperfection of markets, the logic of economies of scale, scope, and experience, as well as the role of technology spillovers to explain how government could protect and invest in national firms in order to maintain a competitive advantage in strategic sectors of the economy (Gilpin, 2001). This theoretical conception of trade policy has broad empirical implications to the extent that it tends to legitimize interventionist policies in the name of economic competitiveness. The rise of China has renewed interest in the so-called 'developmental states' and their ability to shape growth through industrial and trade policies (Rodrik, 2007; Haley and Haley, 2013). Today, as in the 1980s, when Japan's economic surge threatened American competitiveness, sector-specific policies ranging from government subsidies, nontariff barriers, and export promotion are once again a source of both envy and anxiety toward the so-called 'unfair trade.' Amid these

political debates, political economists have, however, shattered conventional dichotomies between strong and weak states, revealing, for instance, that the United States has long played an active role in supporting the private sector, not least with protectionist or interventionist trade policies (Block, 2008; Chang, 2003; Weiss, 1998).

While this approach confers great responsibility to decision makers, a second school of thought has devoted greater attention to the institutional constraints under which they must operate. For institutionalist scholars of foreign economic policy, the formation of domestic structures has a durable impact on politics as it restricts future policy choices and potentially shapes ideas and coalitions (Katzenstein, 1978; Gourevitch, 1978; Goldstein, 1994). As Goldstein writes, "policy is path-dependent: the world does not start anew at each decision point. Rather, history builds an ever-more-complex web of interests, ideas and policies" (1994: p. 22). In short, institutions shape the orientation of trade policy, while institutional changes occur primarily in exceptional circumstances such as periods of crises (major wars, deep recessions, etc.) (Ikenberry et al., 1988).

For instance, in the United States, the Reciprocal Trade Agreements Act of 1934 has been largely held as a catalyst for the adoption of liberal trade policies. Indeed, by transferring the tariff-making authority from the legislative to the executive, it redefined the relationship between business and government. This power shift was renewed with the creation of fast track authority in 1974, which delegates trade-negotiating authority to the executive branch, and has arguably helped to shield the decision-making process from pressure groups (Destler, 1986; Haggard, 1988; Goldstein, 1994). On the other hand, free trade institutions have coexisted not only with older protectionist institutions such as the US escape clause, but also with the resurgence of protectionist remedies in the last quarter of the twentieth century, giving rise to a 'hybrid' trade policy that promotes both trade liberalization and protective tariffs in certain sectors (Goldstein, 1986).

A common grievance addressed to institutionalism is that it is a poor predictor of change. Indeed, by themselves, institutional factors are nothing more than intervening variables. They are only relevant because they can affect the mobilization of political actors on behalf of policy innovation. On the other hand, and as some statist theorists acknowledge, institutions are also 'malleable' and can be instrumentalized by decision makers (Haggard, 1988; Ikenberry, 1988).

As Ikenberry notes, "in terms of explaining foreign economic policy, the institutional approach can provide only some of the answers" (Ikenberry, 1988). To be useful, institutional and societal forces must, therefore, be combined. Finally, the study of trade policy formation must also account for the interplay between the domestic and international levels of analysis, an intellectual undertaking best encapsulated in two-level games.

Two-Level and Multiple-Level Games

While economists and institutionalists provided crucial insights into the internal dynamics of policymaking, international relations scholars have encouraged students of trade policy formation to consider both domestic and international factors. The seminal contributions of Bruck et al. (1962) and Gourevitch's *Second Image Reversed* (1978) represented two early attempts to analyze the interaction between domestic politics and the international environment. Gourevitch posited that international events were not only the reflection of domestic structures – 'a second image' – but also a source of political change at the state level: a 'second image reversed.' Both Bruck et al. and Gourevitch's analyses included a wealth of variables: structural, societal, and even ideational factors at the domestic level; institutional and power-related determinants at the international level.

Putnam (1988) built upon the work of his predecessors to formulate a more parsimonious theory. His analysis of international economic negotiations at the Bonn Summit of 1978 has since become a classic in international relations. For Putnam, international politics can be conceived as a two-level game: at the national level (Level II), domestic actors pursue their interests by pressuring the government, while politicians seek political support by building coalitions; at the international level (Level I), national governments strive to satisfy their domestic constituencies, while minimizing the adverse effects of foreign developments.

Within his framework, the decision-making process hinges on a 'win-set,' defined as the set of all possible international agreements that would obtain the necessary majority among domestic constituencies. For Putnam, the size of this 'win-set' is crucial to the outcome of negotiations. Larger win-sets are more likely to be successful, i.e., to lead to international cooperation. Conversely, smaller win-sets, whether real or simulated by negotiators, are more difficult to overcome and, thus, likely to confer more bargaining power to state actors. What forces shape win-sets? Here, Putnam points to three factors: domestic politics, state institutions, and the strategy of international negotiators. Despite his emphasis on the significance of domestic politics, Putnam does not exclude the possibility of a 'second image reversed.' In fact, his concept of 'reverberation' posits that international pressures can impact the domestic sphere. Putnam provides a robust theoretical toolbox to understand the complex dynamics of trade politics, insofar as it synthesizes many elements of the society-centered and statist approaches.

As a result, it has become a popular framework for the study of trade policy formation, particularly congenial with intergovernmental negotiations. For instance, two separate studies of the negotiations on NAFTA show that two-level games are particularly well equipped to analyze North American trade politics (Cameron and Tomlin, 2002; Mayer, 1998). However, Putnam's analytical framework shows less explanatory power when applied to intergovernmental negotiations within well-established international organizations like the European Union. Indeed, not only do 'two-level games' ignore the autonomous role of supranational institutions in agenda setting, but they also disregard the hypothesis that national governments might instrumentalize international negotiations to pursue unpopular domestic reforms that fall outside their win-sets. This is all the more important in the trade policy sphere, where national governments have delegated their negotiating authority to the European Union. To remedy this problem, scholars have expanded Putnam's framework into

a 'three-level game' that incorporates the logic and dynamics of supranational institutions (Moyer, 1993; Patterson, 1997). In doing so, they renewed with the neo-functionalist tradition of Ernst Haas (1958), who studied the role of transnational actors and supranational officials to understand the self-reinforcing process of European integration. Others have developed multilevel analyses to account for multiple factors including subnational groups, supranational actors, or transnational advocacy networks (Smith and Ray, 1993; Hinojosa-Ojeda, 2002).

The Future of Trade Policy

These sophisticated models illustrate the growing complexity of the trade policy process in the globalized economy, a policy sphere that is no longer confined to tariff duties. The challenge of negotiating far-reaching agreements under the unanimity rule of the WTO – illustrated by the failure of the Doha Round – has led some countries to pursue trade initiatives at the bilateral and regional levels that may be more attuned to their economic interests and worldviews (Krist, 2013; Lynch, 2010). Amid the proliferation of regional trade agreements, two competing varieties of regionalism have emerged. One model, defended aggressively by the United States and Europe, aims to promote comprehensive agreements that go far beyond conventional tariffs to tackle complex issues such as regulatory coherence, digital trade, and state-owned enterprises. This deeper form of integration contrasts with China's policy of noninterference and the more circumscribed nature of its multiple trade initiatives. Without a revival of multilateral trade negotiations, the future of trade policies is likely to be shaped by these competing models. More than a complex bureaucratic apparatus, the debates surrounding trade policy are in essence a battle over the norms and rules of economic globalization that will be shaped by the dynamics of the world economy; the geopolitical tactics of competing nation-states; and the social and economic interests of producers, workers, and consumers.

Trade Unions and Social Work: Lessons from Canada

Winnie Ng, CAW-Sam Gindin Chair in Social Justice and Democracy, Ryerson University, Toronto, ON, Canada

Abstract

This article argues that the rise of new managerialism and new public management has taken the 'worker' out of social work, to the extent that the field has lost its historic connection to social justice. The need for solidarity between social workers and unions is urgent in the face of rising neoliberalism and austerity agendas that threaten to undo fundamental social reforms. Through historical examples and case studies, and with an eye toward the importance of equity, this article proposes means for building new community–labor alliances through a critical linkage between social workers as professionals and trade union activists.

Introduction

Setting the Broader Context

Globally, trade unions, public services, and the public at large are bearing the brunt of the deep cuts in social spending, job reductions, outsourcing, and related deficit reduction measures. In the present economic climate (termed 'gloves-off' by Bernhardt et al., 2008), where managerial flexibility and corporate profit margins take precedence over the needs of working people, global labor market restructuring threatens to have serious impacts on workers, their families, and their communities (Berberoglu, 2011).

The dominant political narrative of the austerity agenda has been a 'blame game' – blaming the victims, blaming others who are more vulnerable; blaming anyone (such as union bosses and environmentalists) who can be construed as threatening profit maximization or making business less 'efficient.'

At the same time, the serious funding reductions in social services have ushered in a new era of commodification of services (Dominelli, 2004). Social work services are increasingly under threat and undermined. As a result, people in poverty end up having less access to public services. In the context of a gendered and racialized labor market (Galabuzi and Block, 2011), the intersectionality of race, class, gender, and other forms of systemic oppression is reflected in who bears the brunt of this global race to bottom.

Given the adverse impact of the austerity agenda on both the labor movement and social work, this article explores what trade unions and social work share, and reimagines the conditions for possible convergences between the two. Finally, this article considers the strategies that social workers in the dual roles of social work practitioners and trade union activists can carry out to create a collective narrative of resistance.

The Need for Renewal and Convergence between Trade Unions and Social Work Practice

Within the Trade Union Context

There has been a massive erosion of public sector employment. In Canada alone, the Federal government has eliminated 25 000 jobs in past year. The other pressing challenge is the legislative attack on union recognition such as the Rand formula in Canada and right to work legislation in the United States. In November 2012, the American State of Michigan became the 24th state to pass 'right to work' legislation which weakens union membership and provides a pretext to lower wages.

Over the past two decades, with the decline in union density, labor scholars have raised the urgent need to reverse the trend and proposed new organizing strategies to reach women, youth, racialized, and immigrant workers (Kumar and Schenk, 2003; Briskin, 2006). However, studies have also shown that recruiting new membership without meaningful engagement can be problematic and there is a need for labor to democratize the internal union practices for stronger member participation (Murray and Levesque, 2005; Bernard, 2006).

Trade unions, as a microcosm of a society where sexism, racism, and other forms of systemic discrimination are reflected in everyday practice, also find themselves being challenged on their policies and practices of exclusion by their own membership. The vision of building an interracial working-class movement for social justice and solidarity has also been put forth as part of the critical dialogue on labor renewal (Gasper and Fletcher, 2008; Ng, 2012).

Within Social Work Context

The austerity agenda has social workers juggling the ideals of social justice and inclusion with the harsh realities of reduced funding. Government funders have imposed restrictions on the amount of advocacy work that agencies can do, as well as further restrictions on welfare benefits, unemployment insurance, and other 'safety net' features of the so-called welfare state. These austerity measures have been imposed throughout the West – in the United States and Canada, to be sure, but also in Spain, Portugal, Greece, Cyprus, and Italy, among others. Such restrictions have caused agencies to self-censor or even retreat entirely from advocacy work, which is now deemed 'too political' (Carniol, 2010).

The new approach to service provision means clients are 'case managed' rather than empowered and social workers are 'micro-managed' as if they were piece-workers in the manufacturing sector. Service providers are pressured to process more cases, rather than do more good, to justify their

funding. At the end of the helping process, clients are never engaged as autonomous agents, only as passive recipients of services.

Very often, the clients of service providers are workers who have lost their jobs due to plant closures and are now seeking help through a traumatic period of transition. Not only is there a total erasure of the former identities and experiences as employees, union members, or activists, there is an absence of collective work that probes the root cause of these problems. Fisher and Shragge (2008) have been critical of such social work practice and urge community organizations to embrace the model of social action organizing that will deal with underlying issues, create opposition, and challenge the status quo. On the other hand, one wonders how many social workers will identify with Donna Baines' stance that unions are an effective vehicle for antioppressive resistance (2011) and suggest union organizing to their clients as a possible course of action.

Edward Scanlon and Scott Harding (2005) suggest the potential for social work to 'reconnect' with organized labor, based on shared fundamental values and the history of the early days of social work. The social work profession needs a political ally if it is to be successful in advancing the historical progressive vision of the profession, and protect social programs from current cuts or threats. The same sentiment is poignantly expressed in the statement of the Social Worker Action Network (SWAN) based in United Kingdom (http://www.socialworkfuture.org/):

> We believe the role of the unions is crucial given the attacks that are looming in the public sector where no area of social work is likely to go unscathed. We will all be blamed for the crisis rather than the target setting, caseloads, staff shortages, bureaucracy and IT pressures that are currently dominating all areas of our practice.

The Deep Historical Roots of Collaboration and Shared Values

The labor movement has always acknowledged unequal power relations in the workplace and in society at large and recognized that countervailing power can come from organizing, mobilizing, and agitation. Employers have been unwilling to relinquish or share their control and power in their workplaces. In North American labor history, worker-oriented legislation and social programs were won as a result of protest, civil disobedience, and working-class solidarity (see, e.g., Hicks and Swank, 1992).

May First as International Workers Day originated as a way to commemorate the workers killed in agitating for an 8-h work day in Chicago in May 1886. In Canada, the General strike of Winnipeg in 1919 is a testimony to workers' courage when skilled trade workers protested about unemployment after WWI. The Trek to Ottawa in the 1930s was initiated by unemployed workers as a response to the intolerable conditions in the work camp set up by the Federal government during the recession. As a result, unemployment insurance benefits were legislated in 1936. Through the years, other key social reforms such as pensions, worker's compensation, universal health care, occupational health and safety, employment standards have all come partly as a result of labor and community mobilizing.

A social justice orientation within social work has deep historical roots in mobilizing and organizing for progressive change (Benjamin, 2011). Throughout these and other milestones in workers' struggles, social workers as community advocates walked side by side with organized labor, a tradition that lives on today, for example, in the 'radical social work' movement in the United Kingdom (Lavalette, 2011).

During the Great Depression, a 'rank and file' movement of social workers emerged. Swelling to as many as 15 000 members by 1936, the movement was a force to be reckoned with. Rooted in the Marxist class analysis, the rank and filers identified themselves as white-collar workers and were strong supporters for the rights of white-collar workers to organize unions. Similarly, founders of the settlement house movement such as Jane Addams, Lillian Wald, and Florence Kelley established the National Women's Trade Union League in 1903 and worked closely with organized labor in advocating for strong, progressive social and public policy and services. As a result of these formidable alliances, far-reaching social and labor legislation – the Social Security Act and the National Labor Relations Act – were passed in the United States during this period (Scanlon and Harding, 2005).

However, after the post-WWII era, the relationship between organized labor and social work grew tenuous as unions partially retreated from activism during McCarthyism. And social workers also retreated for fear of being targeted politically. Many moved along the path of professionalization and 'cultivating' a middle-class professional identity. Instead of pursuing union organizing strategies, priorities were placed on the professionalization of social work, such as advanced clinical training, the development of professional journals, and the formation of professional association of social workers (Walkowitz, 1999). The resurgence of activism in the 1960s and 1970s only partially rekindled social work's reformist zeal. Today's social workers are, in general, more engaged in mainstreaming the social work profession and have left the notion of the 'worker' in social work behind. Others, of course, have retained a social justice orientation and got involved in the civil rights movement, the women's movement, antiwar protests, and, more recently, environmentalism and the movement for marriage equality and LGBT rights.

Community–Labor Alliances and Best Practices in the Mobilization for Social Justice

For the past three decades, some of the more progressive trade unions have recognized the need to build broad-based community coalitions as part of the resistance to the austerity agenda. Coalitions are able to provide a shield for community agencies participating on broader shared goals, without being targeted or running the risk of defunding. Peter Leonard refers to such coalitions as a 'confederation of diversity' where the politics of difference are incorporated with the politics of solidarity (Leonard, 1997; Mullaly, 2002). Four examples of successful coalition building are discussed below: the women's movement's involvement in trade unionism, the mobilization

for employment equity legislation, the minimum wage campaign, and the Solidarity City Campaign.

One key example of community–labor alliances has been through women who are active in both the labor and feminist movements. The influx of women into the public sector in the 1970s enabled activists in the women's movement to use their trade unions as another site to challenge gender discrimination in workplaces, unions, and the broader society. As a result of their commitment, progressive and inclusive policies such as childcare, pay equity, and initiatives to end violence against women were given voice and in many cases then legislated into broader social change.

In the late 1980s, trade unionists in Ontario, Canada, came together with women's organizations, people of color, people with disabilities and Indigenous Peoples to create the Alliance for Employment Equity. The advocacy work of this Alliance, which addressed systemic and discriminatory barriers to employment, led to the passing of the first ever mandatory employment equity legislation in 1993.

The successful mobilization around the minimum wage campaign in Ontario is another example of community mobilizing and political bargaining. The Toronto Workers Action Centre, a community-based agency providing advocacy services for low-wage, nonunionized workers, began the mobilizing and campaigning for a minimum wage raise after a 10-year freeze under a conservative regime. Their campaign was strengthened by a targeted mobilizing effort by the Toronto and York Region Labor Council in forging a broad-based coalition and groundswell of support (Vosko, 2012–13).

On 21 February 2013, the Toronto City Council passed a historic motion to provide services to residents without full immigration status or documents. This work was organized by members of Solidarity City Network which is composed of many community workers and activists from many frontline service providers, legal clinics and antipoverty organizations and immigrant rights advocacy groups.

The above examples of community and labor collaboration speak to the power in numbers. However, the mobilization of these alliances is not without tensions and contradictions when coalition partners have to work outside their comfort zones, being challenged to work across differences. Sometimes, partners come to the table for the sake of appearances while others (who come with financial contributions) can be overzealous in taking up space and claiming credit. Resolving some of these moments of tensions through critical antioppression social work practice has provided invaluable lessons of deepening relationships and solidarity building.

Lessons from the Los Angeles Immigrant Labor Activism

The successful collaboration between labor and community can be best demonstrated by the mobilization of Latino immigrants in Los Angeles (LA) County. Due to deep organizing over the past 15 years, LA has gained over 60 000 new, predominately Latino, unionized workers, bringing new energy and vision to the American labor movement (Milkman, 2012).

Ruth Milkman's (2012) study argues that the LA success in organizing immigrant labor is explained by three overlapping approaches to organizing. The first involves traditional trade union organizing. Several leading U.S. unions have organized Latino immigrants employed in low-wage janitorial, retail, and hospitality work. The Justice for Janitor campaign launched by Service Employees International Union (SEIU) is a prime example of a more innovative organizing approach of direct action and sectorial city wide coverage rather than being restricted to a single workplace.

The second approach within immigrant labor activism is the advocacy and organizing efforts of labor-oriented worker centers. These centers, which number more than a 100 nationwide, provide advocacy, support, and mobilization to workers in precarious employment or in the informal sector (Fine, 2006).

Finally there is the broader immigrant and migrant rights movement and its organizing. This too involves a broad-based coalition including partners from churches, ethnic organizations, community agencies, and organized labor. Foregrounded by the vision of human rights, the coalition has worked for legal status as the panacea to improve immigrant workers' employment and working conditions (Milkman, 2011).

The synergy of the three interlocking strategies has bonded immigrant workers into a cohesive group with a class identity grounded in their common experiences of exploitation and exclusion. It has dispelled the myth commonly held by unions that immigrant workers cannot be organized (Tattersall, 2009). Mobilization has also politicized workers and transformed members of the Latino community into a powerful political and voting bloc that U.S. political parties have had to take notice of.

Social Workers as Professionals and Union Members

The ideal of social work practice as a caring profession that fosters social justice has been greatly undermined by the rise of the new managerialism where service standardization and performance management models are now repacked and introduced into the social services sector as New Public Management (NPM) (Baines, 2011). With multitasking and casework overload, social workers are either being pushed to have more qualifications, or they experience deskilling and devaluing of their work at the other extreme. Dominelli (2004) urges for social workers to break from "the shackles of a government-imposed bureau-rationality that has turned them into bureau-technocrats."

Unionization provides an alternate forum for social workers to exercise their commitment not only to improve their own working conditions, but also to advocate broad public policy change. Collective bargaining has been effective in countering the pace of restructuring in the social services sector. For example, one community agency in Toronto has secured a no-contracting-out clause in their collective agreement and set a precedent in the sector.

Others have used the contract negotiation process to raise work restructuring issues that are detrimental to the quality of care and well being of their clients. Tara La Rose's (2009) study of the strike of a child welfare agency describes how the workers, who were members of the Canadian Union of Public Employees (CUPE), went on strike for 6 weeks after the management refused to address the issue of heavy caseloads

and high levels of stress experienced by their members. Through the bargaining and strike process, workers developed a strong bond, exercised their collective power as union members, challenged state managerial policies, and created positive social change (La Rose, 2009). The hard-won gains such as caps on caseloads and improved workload contract language have set a precedent for child welfare agencies across Ontario (Baines, 2011). The empowerment of these workers through the strike exemplifies the spirit of the union slogan – "collectively we bargain, individually we beg!"

Another successful example of collective resistance comes from a group of social workers who work for a social service agency in Toronto and belong to the Ontario Public Services Employees Union (OPSEU). Ben Carniol (2010) provides a vivid account of how Lisa Quarta, a clinical social worker and the President of her local, organized to stop management from dismissing housekeeping and clerical staff who were predominately racialized women, to cut costs. Quarta first called a union meeting where all affected workers shared their stories and reactions about the pending dismissals with other union members, who were mainly white professionals. As a result, staff members showed up to the subsequent meeting with management wearing black as a way of protesting. Two days later, management backed off the restructuring scheme. Not only did this collective action succeed in saving jobs, it also built solidarity and bridged the divide between racialized members who were in the lower, entry-level positions and white professional members (Carniol, 2010).

The challenges for trade unions representing social workers are twofold. Firstly, as a female-dominated sector, how can unions engage more social workers, when women social workers are often juggling the responsibility of caring for their families with overfull caseloads? Secondly, how do we create transformation at the local union level, where it is closest to the membership? There is great need for rank and file membership to experience transformative moments as union members (Bernard, 2006).

In labor organizing, a key goal is to persuade workers to think less about 'I' and more about 'We.' Organizing does not stop when the workers sign their union cards. They must also develop a sense of engagement and belonging. The following example from the Chicago Teachers Union offers insights on the practice of organizing from the inside outward to involve the wider public.

The Work Behind the Successful Chicago Teachers' Strike

On 10 September 2012, the Chicago teachers went out on strike for 9 days and were able to win public support to stop the austerity moves proposed by the Mayor. It took everyone, including the leadership of the labor movement, by surprise, but the seeds had been planted 2 years earlier when Karen Lewis was elected President of the Chicago Teachers' Strike (CTU) on a platform to "change this into a democratic union responsive to its members" (Sokolower, 2012).

Instead of employing a model of traditional leadership that stifles opposition, the leadership reached out and listened to the diverse opinions of the membership. The CTU rank and file activists were (and are) involved in their local school community, working with parents and other community members on specific issues. Through such involvement, a strong bond between parents and teachers was built. When the strike came, this bond was reflected in widespread parents' support for the teachers' action. This mobilizing approach is very much reflected in Karen Lewis' stance (Sokolower, 2012):

> It all comes down to how you teach people to fight with the tools they have. We have been fighting with the bosses' tools. We can spend a lot of time doing legislation. I think that's fine – have a legislative approach. But understand that you don't control that process….You need to have good relationships with legislators; you need to have members get in touch and let them know what's important to you. That's one tool. But it's not the only tool. Our best tool is our ability to put 20 000 people in the street. I don't care if one rich guy buys up all the ad space. The tool that we have is a mass movement. We have the pressure of mass mobilization and organizing.

What is interesting about this case is that community involvement and mobilization extended long past the resolution of the strike. Six months later, CTU and a coalition of students and parents staged a mass community protest against the closure of 54 schools affecting more than 30 000 students, primarily in low-income black and Latino areas. Networks of Faith, Community and Teachers for Students (FACTS) had sprung up throughout the city to stop the closures.

The Union's leadership also vowed to launch a voter education campaign and send organizers to neighborhoods where schools were slated to close and register a minimum 100 000 new voters. Such action speaks to what Mullaly has referred to as a political strategy to 'relegitimate the state' and "build more rather than less government involvement in social, economic and human affairs" (2002: p. 202). It underscores the importance of moving from the traditional practices of electoral politics to building broad-based coalitions where the inclusion of marginalized groups is meaningful and real. These activities allow a deeper relationship building whereby trust and commitment to each other come to be based on shared values and struggles.

Translating Progressive Core Values into Meaningful Practice

The progressive core values that trade unions and social work share is grounded in a critical analysis of the various ways that social structures, power dominance, and privilege are constructed and in learning to question who benefits from any particular set of social relations. It is also about finding new ways of challenging unjust social relations (Carniol and Del Valle, 2010) and transforming them into equitable processes based on economic, political, environmental, and social justice (Baines, 2011; Benjamin, 2011; Carniol and Del Valle, 2010; Dominelli, 2004).

In reimagining possible new convergences to resist the austerity agenda, it is critical to translate some progressive core values into meaningful practice. For further collaboration and bridging between trade unions and social work, I offer the following three ideas for consideration.

First is advice for trade unions about handling complaints and grievances. Very often, in the expediency of time and resources, union representatives end up resorting to the shortest route to resolve or mediate individual cases, without making deeper connections between the incidents and the larger structural context. Potential cases of harassment and/or differential treatment based on sexism, racism, and other grounds of discrimination are often complicated and difficult to prove. These cases require empathy, skills, and time for the local leadership to take such complaints seriously and respectfully. For a union member from one of the equity-seeking groups, who has finally mustered enough courage to step forward, the support and encouragement offered by a shop steward will make a world of difference and bring them closer to the union family. These can be powerful and transformative moments of union building.

A second recommendation is for the social work profession to reinforce the clarity of social justice and put the notion of *worker* back into social work. The primary entry point for this transformation is through social work education – by integrating social action organizing as a major element in the curriculum, and having a stronger presence of workers' struggles and trade unions in it. I would argue that social work student placements in unions should be expanded, to create a critical mass of such students, dispelling some of the myths about unions, and facilitating a deeper understanding and relationship building for future joint opportunities.

Last is the need to glean lessons from past community and labor collaboration. The conditions to deepen the roots of these community and labor alliances are more horizontal democratic practices that are bottom-up; a transformative leadership that has the political will and courage to challenge the status quo; a commitment to empowerment; and mobilizing strategies that will move people from the comfort of their own silos to the larger space of building the 'We.'

It is in the vision of rebuilding the 'We' that there is a need to probe deeper into the nuanced notion of community unionism and the complexity of movement building for social justice. If the end goal for community unionism is only to broaden the unions' reach to potential membership or to 'rebrand' unions in a more contemporary image, the effort will rapidly dissolve into self-interest and competition. Trade unions in social movements need to go beyond a narrow economistic focus and define themselves by demonstrating their capacity to connect with life experiences under capitalism (Fairbrother, 2008).

In the new norm of workplaces with precarious and informal labor, where workers are no longer confined to traditional workplace settings, it is important to build a repertoire of practice that will reach out to marginalized workers. Dae Oup Chang's study (2012) of the organizing efforts of workers in precarious employment in four East Asian countries proposes an alternate vision of the labor–social movement, where the anchoring is shifted from unions as the site of growth to a community where precarious and marginalized workers, regardless of status and workplace, all come together as an united force. In these community settings, social work practitioners can play a pivotal role in mobilizing to overcome fragmentation in the social sector. They can potentially represent a different path of coalition building that offers a more genuine partnership, empowerment, and innovative practice for social transformation.

Abstract

A trade union is an organized association of workers formed for the protection and promotion of their common interests. The standard view of unions is that they are monopoly organizations that improve the welfare of members, principally by raising wages above the competitive level. For a union to be able to increase wage rates above the competitive level, there must be some surplus that can be shared between the firm and the union, and the union must have some bargaining power to induce the firm to share this surplus. This article investigates the conditions under which a union can increase wages and explores ways of modeling the competing preferences of unions and management. The article also notes the arguments suggesting that, in the presence of imperfect information and uncertainty, unions may enhance efficiency. To the extent that unions reduce labor turnover and negotiating costs, they may increase the available surplus to be shared between parties.

Trade Unions

A trade union is an organized association of workers formed for the protection and promotion of their common interests. The standard view of trade unions is that they are monopoly organizations that improve the welfare of members, principally by raising wages above the competitive level. This article investigates the conditions under which a union can increase wages, and explores ways of modeling the competing preferences of unions and management.

Before beginning, we briefly discuss trends in two measures of union power – union density and union coverage – over the period 1990 to the most recent year for which these data are available. Table 1 shows the figures for the OECD countries.

While in 1990 trade union density averaged 40.1% across OECD countries, by 2009 it had declined to 28.5%. (These figures come from the OECD database on trade unions and Visser, 2011.) (Trade union density refers to the number of trade union members as a percentage of wage and salary earners.) While this is a large drop, the averages conceal considerable heterogeneity across countries. For many countries, the influence of trade unions at the macroeconomic level is better indicated by the extent of union coverage of the workforce, rather than by union density. (The definition of the collective bargaining coverage rate is the number of workers covered by wage bargaining agreements as a proportion of all wage and salary earners.) Across OECD countries, union coverage averaged 70% in 1990 and declined to 62% two decades later. Nonetheless, there are still some countries in which both density and coverage are low. For example, Table 1 shows that in the US only 11% of the workforce belong to a union and only 14% are covered by union collective bargaining.

Given that union density is declining in most industrialized countries, and that in many countries only a minority of the workforce is covered by unions, do we really need to worry about providing appropriate models of trade union behavior? One answer is that union bargaining models are generalizable and hence more widely applicable. Indeed, union contracts may be viewed simply as an explicit formulation of a wider variety of labor contracts that are found in many labor markets. Where nonunion firms face an incumbent workforce with a degree of bargaining power, management and workers may be in a situation of bilateral monopoly that can be

characterized by a union-firm bargaining model. Moreover, the *threat* of union organization of a nonunion sector may provoke management to provide wages and working conditions that mimic those negotiated in union firms.

Conditions Under Which a Union Can Improve Workers' Welfare

For a trade union to be able to increase wage rates above the competitive level, there must be some surplus that can be shared between the firm and the union, and the union must have some bargaining power to induce the firm to share this surplus.

Bargaining Power

Union bargaining power derives from the ability of the union to inflict damage on the firm by withdrawing labor. This works when there is no substitute pool of nonunion workers, for example, if there are high labor turnover costs or if the union controls labor supply through entry restrictions or through having high levels of membership relative to the size of the sector. Union membership density may play a part in determining the power of the union to extract from the firm a share of any rents. As membership density increases, there is a shrinking pool of workers available to the firm should it choose not to employ union labor. Thus one would expect to find a minimum critical level of membership below which firms would refuse to recognize and bargain with the union (Osborne, 1984). Where membership density is crucial to the union's monopoly power as, for example, with the historical emergence of the general unions, the union must consider how to attract workers at the margin. The basic problem for economists in explaining why workers join a union relates to the free-rider problem, arising because of the collective nature of many of the goods provided by the union (Olson, 1965; Booth, 1985). Why join the union when union dues are costly, and when the benefits are not immediately available or apply to all workers regardless of their union status? Of course established unions may also provide incentive private goods that encourage workers to unionize. Indeed, a union can act as the workers' agent, since it can reduce the costs of negotiation and processing of grievances, a role which may also be useful to employers (Faith and Reid, 1987).

Is There as Surplus to Be Shared?

Even if a union controls labor supply, it will not necessarily be able to negotiate a large wage increase relative to the competitive level. The magnitude of the union wage depends crucially on the elasticity of labor demand in that sector. There can be little doubt that, if unions emerge in competitive markets, high union wages introduce allocative inefficiencies into the economy through the distortion of factor prices. Without unions, allocative efficiency is associated with the equalization of the marginal products of identical factor inputs across sectors. With higher wages in the union sector, union firms employ fewer workers. Displaced union workers crowd into the nonunion sector, lowering wages there. As a result, too few workers are employed in the union sector where output falls, while too many workers are employed, and too many goods produced, in the nonunion sector. There is a deadweight efficiency loss, because the value of marginal products in the two sectors is not identical. In addition, there are distributional issues to consider, and longer run effects due to substitution of capital for labor. Furthermore, in unionized sectors there may be under-investment in capital through the hold-up problem (see, for example, Grout, 1984).

This discussion of allocative inefficiency assumes that the union has emerged in an economy characterized by competitive product and labor markets. But there is considerable evidence that, in modern industrialized countries, many product markets are characterized by imperfect competition. Moreover, nonunion firms may also face an incumbent workforce with a degree of bargaining power (Lindbeck and Snower, 1988). Thus, even in the absence of unionization, management and workers may be in a situation of bilateral monopoly. The majority of formal trade union models in the literature assume a perfectly competitive product market to allow the models to focus on wage and employment determination in the simplest environment (exceptions are, inter alia, Dowrick, 1989; Dobbelaere and Mairesse, 2013). Nonetheless, it is an empirical regularity that imperfections in product and labor markets are correlated (Stewart, 1990).

Even within the competitive model, there are arguments suggesting that, in the presence of imperfect information and uncertainty, unions may enhance efficiency. To the extent that unions reduce labor turnover and negotiating costs, they may increase the available surplus to be shared between parties (Freeman and Medoff, 1984). Of course, there may be interdependence between the monopoly and efficiency roles of trade unions: unless the union has some bargaining power, it may be unable to increase efficiency.

Formal Modeling of Union Behavior

To investigate union behavior, the economist needs to model the objectives of the relevant actors involved in wage setting, as well as the means of resolving their potentially conflicting objectives. Most union models consider the objectives of two agents – the union and management. Typically, the government's behavior is assumed exogenous. Because the objectives of union and management may be conflicting, models need to consider how conflicts might be resolved within the constraints provided by the institutional environment. The range of issues covered by collective bargaining in Europe is narrower than in the USA, which probably reflects a relative lack of US social welfare legislation. (In Europe, legislation typically covers issues such as health insurance, pensions, redundancy pay, and unfair dismissal that are often covered by collective agreements in the US.)

While bargaining may take place over a number of issues, for tractability researchers typically concatenate wages and other forms of compensation, such as fringe benefits, under the single heading of wages. Union preferences appear to include employment as well as wages, but it is rare to find instances of the union and the firm bargaining over both wages and employment. Of course, unions affect employment

indirectly, not only through increasing wages but also through negotiation over staffing levels, recruitment, and redeployment.

While unions typically have a number of goals (from increasing remuneration to broad political aims concerning the labor movement as a whole), the orthodox union model assumes unions are concerned only with the unionized sector. But a union typically comprises heterogeneous individuals with varying and possibly conflicting preferences as to the union's strategy. For example, there may be principal–agent problems arising because union leaders (agents) have objectives that may conflict with the membership (the principal). The leadership may be better informed than its membership, or perhaps interested in self-aggrandizement or in wider labor goals. Unions are usually large, with complex organizational structures concerned with representation of members' interests and with administration. Because the internal organization of the union is typically hierarchical in structure, the question arises as to how well members' preferences are transmitted through the various levels, each of which may have conflicting aims. Moreover, there is heterogeneity across unions in terms of their structure and constitution (ranging from the democratic through to the totalitarian) that may determine a union's maximizing strategy.

While there is a small literature allowing for union objectives to be affected by membership heterogeneity or a conflict of interests between leaders and members (Farber, 1978; Blair and Crawford, 1984), the widely used models of union behavior side-step these problems by supposing that all workers in the union sector are identical and are union members. They also assume that the union cares only about the economic welfare of the union sector. For simplicity, union-negotiated benefits are assumed to be encapsulated in the wages variable. Because the union is also hypothesized to care about the employment of union workers, union objectives can be specified as an increasing function of wages w and employment n.

In most union literature, the union is assumed to maximize either a utilitarian objective function, or an expected utility objective function. The utilitarian objective function assumes that the union maximizes the sum of the individuals' utilities. The union comprises identical members treated identically by the union, and therefore in this context no distributional or normative judgments are being made by the utilitarian objective. However, if workers were assumed heterogeneous, the use of this as the union objective would introduce normative judgments (since if individuals were not identical, it would be necessary to consider why the utilitarian social welfare should be adopted instead of some alternatives such as the Rawlsian or maxi–min criterion, or a more egalitarian approach). If the union's wage-setting behavior results in some union members being unemployed, the utilitarian objective function is:

$$U = nu(w) + (t-n)u(b) \quad w > b;\ 0 < n \le t \qquad [1]$$

where $u(.)$ is a concave (indirect) utility function, w denotes wages, n denotes employment in the union sector, t is the total number of union workers in the sector (and membership by assumption), and b is the alternative sector wage or the unemployment benefit.

The second popular union objective function is the expected utility function. If membership is fixed, eqn [1] can be written equivalently in terms of expected utility. Since the union raises wages above the competitive level, each member faces some probability $(1-n/t)$ of being unemployed. If unemployed, a worker receives the alternative sector wage or the unemployment benefit. The expected utility of a representative union member is given by:

$$E(U) = \frac{n}{t}u(w) + \left(1-\frac{n}{t}\right)u(b) \quad u'(w) > 0;\ u''(w) \le 0 \qquad [2]$$

where $u'(w) = \mathrm{d}u/\mathrm{d}w$. The slope of the union indifference curve in (w, n) space is found by totally differentiating either eqn [2] or [3] with respect to w and n, holding (expected) utility fixed, yielding $\mathrm{d}w/\mathrm{d}n = -[u(w) - u(b)]/nu'(w)$.

Both the utilitarian and the expected utility objective functions have the implication that identical workers receive different outcomes *ex post*. Employed members receive the union wage, while the unemployed workers receive b. However, if unemployed members effectively leave the union, the leadership will be concerned about future union viability, since there will be a larger pool of nonunion labor that might undercut the union wage, and union income from dues would fall. This is likely to affect union outcomes, and is an argument for inclusion of the level of membership in the union objective function as an endogenous variable. Moreover, b may not be exogenous – the union may affect remuneration for unemployed members through redistribution by benefits or redundancy pay, suitably adjusted for the disutility of work for those in employment. Indeed, historically, many unions paid unemployment benefits to out-of-work members, and some commentators argue that this was important for union growth and survival.

Now consider the behavior of the firm. The necessary conditions for a union to be able to appropriate any surplus in a competitive product market, without driving the firm out of existence, are very high levels of unionization in a competitive industry, no nonunion foreign competition, entry barriers, and inelastic product demand. Without the first three conditions, domestic firms, foreign firms, or new firms entering the industry could simply hire nonunion labor and produce at a lower cost than unionized competitors, thereby driving them out of business. Assuming the firm maximizes profits and has no power in the labor market (which means it will take wages as given), it has just one choice variable – employment. The optimization problem facing the firm is therefore:

$$\max_n \pi = pq(n) - wn\ q'(n) > 0;\ q''(n) < 0;\ q(0) = 0 \qquad [3]$$

where π denotes profits, p denotes product price, and $q(n)$ is the production function characterized by diminishing returns to labor. The firm's wage bill is wn and capital is held fixed. The slope of the firm's isoprofit curve in (w, n) space is found by totally differentiating eqn [3] with respect to wages and employment keeping profits fixed, to obtain $\mathrm{d}w/\mathrm{d}n = [pq'(n) - w]n$. The locus of the turning point of each isoprofit curve traces out the labor demand curve where $pq'(n) = w$, as illustrated in **Figure 1**. Two isoprofit curves IP_0 and IP_1 are illustrated in **Figure 2**, together with two union indifference curves IC_0 and IC_1.

Figure 1 The isoprofit curve.

Figure 2 Inefficiency of the monopoly union model.

The Monopoly Union Model

In the monopoly union model, there is no bargaining between the two parties. Instead, the union acts as a monopolist in the supply of labor and imposes a wage rate on the firm. The firm, however, retains its managerial prerogative to determine the number of workers employed at the union wage. Once the union sets the wage, the firm reads off from the labor demand curve the number of workers to hire at that wage. Thus, a union maximizing the expected utility of its representative worker sets wages as follows:

$$\max_n E(U) = \frac{n}{t}u(w) + \left(1 - \frac{n}{t}\right)u(b) \quad \text{subject to } pq'(n) = w \qquad [4]$$

The first-order condition can be found directly by equating the slopes of the union indifference curve (giving the union's marginal rate of substitution of employment for wages) with the slope of the labor demand curve, illustrated as point A in Figure 2. The monopoly union seeks its highest level of utility, subject to the constraint of the firm's labor demand curve, where w^* and n^* are the optimal wage and employment levels, respectively. It can be seen, from the first-order condition in eqn [5], that wages will be set by the union such that the percentage increase in a member's utility due to a percentage increase in wages is exactly equal to the wage elasticity of labor demand ε. Intuitively, this result arises because an increase in wages reduces union employment, and thus each worker faces a greater probability of being unemployed. On the other hand, any member lucky enough to be employed receives a higher wage. Thus, in equilibrium, the percentage marginal benefit is equal to the percentage marginal cost:

$$\varepsilon \equiv -\frac{n'(w)w}{n} = \frac{wu'(w)}{[u(w) - u(b)]} \qquad [5]$$

This equation simply characterizes the equilibrium situation. To obtain a specific value for wages, it is necessary to choose explicit functional forms for the utility function and the labor demand function that can then be inserted into the generalized characterization and solved for the wage rate. For evaluation of empirical work attempting to test this model, see Pencavel (1991) and Booth (1995). For a more recent empirically relevant formulation of the union objective function see Pencavel (2009).

Using this model, it is straightforward to show how the wage set by the monopoly union alters due to a change in each of the explanatory variables. An isoelastic increase in labor demand has no effect on wages, but employment increases. An improvement in alternative opportunities increases the union wage, but employment is reduced as we move up the labor demand curve. An increase in membership has no effect on wages or the numbers employed. The empirically testable predictions of the monopoly union model are first that the alternative wage and unemployment benefit should affect wages directly. But employment should be determined by the wage rate, and unaffected by variables measuring alternative opportunities. Second, membership changes should have no impact on the union wage.

The Bargaining Approach

Next consider more sophisticated methods of reconciling the different preferences of union and management, using a bargaining approach. It turns out that the monopoly union model is nested as a special case within a simple bargaining framework. While some researchers argue that the monopoly union model is a reasonable approximation for particular industries at particular times, observation suggests that wages are more often bargained over by unions and firms. When union and firm bargain over wages, they are in a bilateral monopoly situation, in which a single seller confronts a single buyer of labor. A vital element in this bargaining is the ability of each agent to impose costs on the other agent if it refuses to bargain and engages in a strike or lockout. Although strikes are relatively infrequent, this does not mean that the strike or lockout is unimportant. It is the threat to withdraw that counts. What induces the two parties to bargain is the threat of facing costs imposed by the other party.

Since the union and the firm are in a situation of bilateral monopoly, additional structure must be imposed on the model to generate a determinate solution of the division of the available surplus between the two parties. There are two broad approaches to modeling bargaining behavior – the axiomatic

or Nash bargaining approach, and the more recent game theoretical approach (Nash, 1950). Under certain conditions, these generate identical predictions in spite of the fact that they proceed from very different assumptions (Binmore et al., 1986).

The solution concept widely used in the union literature is the generalized Nash bargaining solution, according to which wages are determined by maximization of the product of each agent's gains from reaching a bargain, weighted by their respective bargaining strengths. Since management is assumed to retain the right to determine employment unilaterally, this is referred to frequently as the 'right-to-manage' model. Define a status quo or fall-back point for each party as its position if no bargain is reached. For the firm, the status quo is zero, because if it does not reach a bargain with the union workforce, it cannot obtain any other workers since there are no nonunion workers in the sector. So the firm's net gain is simply its profits function. For the union, its status quo for a representative member is $u(b)$, since that is what a member will receive if no bargain is reached. Thus, the net gain to the union is simply the expected utility of a representative member (see eqn [2]) less fall-back utility, given by $[u(w) - u(b)]n/t$.

The generalized Nash bargaining solution (the product of the weighted net gains to each party) can be written as:

$$\max_{w} B = \left\{\frac{n}{t}[u(w) - u(b)]\right\}^{\beta}\{pq(n) - wn\}^{1-\beta} \qquad [6]$$

where β measures the bargaining strength of the union and $(1 - \beta)$ is the bargaining strength of the firm. The solution to this bargaining problem is obtained from the first-order condition of eqn [6], and is given by:

$$\frac{\beta w u'(w)}{u(w) - u(b)} = \beta\varepsilon + \frac{(1-\beta)wn}{pq(n) - wn} \qquad [7]$$

where ε is the wage elasticity of labor demand. The left-hand side of eqn [7] represents the proportional marginal benefit to the bargain from a proportional increase in the wage. Since only the union receives this benefit, it is weighted by the union's bargaining power β. The first term on the right-hand side is the union's proportional marginal cost (the percentage reduction in employment due to the proportionate wage increase) weighted by union power β. The second term on the right-hand side represents the firm's proportional marginal cost, weighted by the firm's power $(1 - \beta)$. If the union has all the power, $\beta = 1$, and the union extracts the entire surplus, the right-to-manage model collapses to the monopoly union model. For $0 < \beta < 1$, the employment and wage outcome will lie on the labor demand curve anywhere between the monopoly union extreme and the competitive outcome. If the firm has all the power, $\beta = 0$ and the wage is then simply the alternative wage b.

The empirically testable predictions of the right-to-manage model are the same as a monopoly union model with the addition of the prediction that variables proxying union strength will affect wages directly.

Is the right-to-manage model Pareto-efficient? (Pareto efficiency is defined by economists as a situation where no one can be made better off without making someone else worse off.) Or can at least one party be made better off by shifting to some other (w, n) pair? In **Figure 2**, the isoprofit curves IP represent different levels of profits for the firm, with higher curves denoting lower profits since they are associated with higher wages. IC denotes the union indifference curves, with expected utility increasing as the union moves northeast. Suppose the equilibrium of the right-to-manage model is at point A. The union could be made better off while keeping the firm on the same isoprofit curve, by shifting to point B. Alternatively, the firm could shift to a higher isoprofit curve, while keeping the union on the original indifference curve, by moving to point C. Both parties could be made better off by shifting from A to any point in the shaded area. Positions on the labor demand curve are thus Pareto-inefficient. Either the union or the firm could be made better off by bargaining over employment as well as wages, allowing them to shift from a point such as A to B or C or anywhere in the shaded area. Efficiency in the context of this model is where the marginal rates of substitution of employment for wages, for both union and firm, are equal.

The Efficient Bargaining Model

Now suppose the union and firm simultaneously determine wages and employment. While evidence suggests that unions and firms do typically not bargain over wages and employment, this approach has been important in the union literature because of its efficiency property beloved by economists. But the fact that this does not appear to happen in practice suggests that there may be something economists are missing in their modeling. (Of course the wage and employment outcome predicted by the efficient bargaining model is inefficient from the viewpoint of society as a whole.)

Efficiency requires only that one party's welfare be maximized subject to an arbitrarily fixed level of welfare of the other. This makes it possible to characterize an efficient outcome simply by considering union and firm preferences, without imposing a particular bargaining structure. While this does not yield a unique outcome, it illustrates the necessary conditions for efficiency. An efficient bargain over (w, n) solves:

$$\begin{aligned} &\max_{w,n} pq(n) - wn \quad n \geq 0;\ w \geq b \\ &\text{subject to } \frac{n}{t}[u(w) - u(b)] + u(b) = U \end{aligned} \qquad [8]$$

From the first-order conditions is obtained the result that an efficient (w, n) pair is given by equating the marginal rates of substitution of employment and wages for the union and the firm. This means equating the slopes of the isoprofit and union indifference curves, illustrated as point C in **Figure 2**, and shown below:

$$pq'(n) - w = -\frac{[u(w) - u(b)]}{u'(w)} \qquad [9]$$

The contract curve is defined as the locus of all points satisfying eqn [9]. Two points on the contract curve are B and C in **Figure 2**. The contract curve is positively sloped for risk-averse workers (but vertical if workers are risk-neutral). From eqn [9], note that the value of the marginal product of labor $pq'(n)$ is less than the wage rate, by an amount that is equal to the marginal rate of substitution of employment for wages. Hence, the contract curve lies to the right of the labor

demand curve for $w > b$. If $w = b$, then from eqn [9] $pq'(n) = w$, the perfectly competitive result. Thus, the contract curve and the labor demand curve coincide where $w = b$. Since for efficiency we only require that one party's welfare be maximized subject to any arbitrarily fixed level of welfare of the other, any point on the contract curve represents an efficient outcome for a particular arbitrarily fixed level of welfare of one agent.

To determine a unique (w, n) pair, a means of obtaining a particular solution to the bargaining procedure must be added to the model. A common approach is to use the generalized Nash bargaining model of eqn [6] modified to allow for bargaining over both w and n. The solution to this maximization problem generates a determinate outcome for wages and employment, which lies somewhere on the contract curve (Leontief, 1946; McDonald and Solow, 1981). In the 1980s considerable attention was devoted to devising ways of testing which model was appropriate for the union sector (Pencavel, 1991).

Many unions are unable to bargain over employment directly, and thus the relevance of this fully efficient model might be questioned. However, unions can often affect employment indirectly, for example, through bargaining over the labor-to-capital ratio, work intensity, or redundancy payments. Johnson (1990) found that, in models in which there is bargaining over wages and the labor-to-capital ratio or work intensity, the wage–employment outcome lies somewhere between the fully efficient and the right-to-manage model.

Conclusions

This article can only give a flavor of the economics behavior of the trade union, and many important topics have been omitted; for example, the impact of unionization on the macroeconomy (Layard et al., 1991; Boeri et al., 2001). Some countries (such as many European economies) have centralized wage bargaining arrangements, while others such as the US are decentralized. It is important that in future work these institutional differences are incorporated into the modeling framework, as discussed in more depth in Boeri et al. (2001) and Cahuc and Zylberberg (2004).

Other important topics omitted from this survey (but covered in Booth, 1995) include the economics of strikes (*see* Dispute Resolutions in Economics), the relationship between unions and hours of work, and the modeling of endogenous union membership, an important topic in countries such as the UK, in which compulsory union membership is illegal. There is also a vast empirical literature estimating the impact of unions on economic performance.

While union membership and power have declined in many industrialized countries from the 1980s (for example, Britain and the US), it is unlikely that unions will vanish all together, especially if they adopt creative coping strategies (Boeri et al., 2001: Chapter 6). Moreover, the evidence suggests that as male membership declines, more women are unionizing. It is also possible that in the future unions may become stronger in Eastern European, Asian, and African countries. It is therefore important for researchers working on the economics of trade unions to consider what form of unionism might be least distortionary in a modern economy. Furthermore, while many models of union behavior refer to explicit labor contracts between a union and management, the models are also relevant to a wider class of situations than those in which a union explicitly represents workers. The models are potentially applicable, with only a few minor modifications, to nonunion labor markets where incumbent workers have some market power and where the firm has economic rents that might be shared.

Abstract

Few concepts have played a more central role in the development and practice of anthropology than tradition. This article opens with an outline of the principal senses in which tradition figures in anthropological thought: as cultural substance, dynamic process, social practice, and authorizing force. The second section traces the historical foundations of these contemporary usage's in enlightenment philosophy, Protestant reformism, antiquarianism, classical and biblical philology, the Herderian synthesis, Romanticism, and the nineteenth- and early twentieth-century typological schemes of Tönnies, Durkheim, Weber, etc. The final section sets out the principal foci of empirical, conceptual, and critical interest in tradition in twentieth-century anthropology: the social organization of tradition; the dynamic inter-relationship between tradition and creativity (especially in the anthropology of art); the relationship between tradition and communicative technologies (especially orality and literacy); and the politics of tradition.

Few concepts have played a more central role in the development and practice of anthropology than tradition. We will first outline the principal senses in which tradition figures in anthropological thought, then trace the historical foundations of these contemporary usages, and conclude with the major lines of inquiry centering on tradition in contemporary anthropology.

Tradition as Substance, Process, Practice

In its most general usage, tradition may be defined as the element of historical continuity or social inheritance in culture, or the social process by which such continuity is achieved. More substantively, tradition refers to the collective social inheritance of particular people, culture, society, group, or collectivity, and as such, stands as the referent of its collective identity. In this sense, tradition is generally conceived of as the aggregate mass of cultural forms – cast as knowledge, beliefs, practical routines, or texts – that are the constituent elements of a culture, handed down from one generation to the next. One may speak also of 'a tradition' as any discrete element or trait within the general mass. Here, tradition takes on the sense of an inherent quality of the past which is diagnostic of traditionality; hence, 'a traditional practice,' 'a traditional belief,' 'a traditional tale,' and so on. So conceived, a tradition assumes the guise of a durable natural object, passed down through time by successive generations of 'culture bearers.'

A more concrete and practice-centered understanding of tradition recognizes that the temporal continuity of tradition is instantiated in successive enactments of cultural forms that are guided by precedent and convention and construed as replicating, in some essential sense, what has been done before. When the focus is on the dynamics of tradition, the process of handing down, or intergenerational transmission, the element of social learning is often emphasized, whether under the rubric of enculturation, which foregrounds the acquisition of cultural knowledge, or the now preferred socialization, which foregrounds the social matrix of the acquisition process.

The conjoint consideration of socialization and tradition tends to foster a conception of intergenerational transmission as the replication of uniformity, in Anthony F. C. Wallace's (1970) apt phrase. This orientation points to what is perhaps the most common theme in anthropological considerations of tradition, that is, its normative force, the notion that tradition enjoins conformity. The binding force of tradition is variously attributed to the force of precedent or habit inherent in the routinized quality of replicated practice, the psychological pressure attendant upon deviating from accustomed modes of thought and action, the moral weight of public opinion, and – most strongly – the power of a coercive apparatus of external sanctions sustained by sacred mandate (as from the ancestors) and intensified by ritual enactment. Where such discriminations are made systematically, they are generally marked by terminological distinctions, as between custom and tradition, with tradition reserved for the most strongly sanctioned and ritualized elements of the social inheritance. In general, however, there is little definitional rigor or regularity of terminological usage in the field; as often as not, terms such as tradition, custom, or folkways are employed as loosely equivalent. In such systematization, again, tradition may be distinguished from law, the former deriving its force from 'the sanctity of immemorial traditions,' the latter from 'the legality of enacted rules,' in Max Weber's classic formulation. Others, however, such as Bronislaw Malinowski, take custom and tradition as more or less equivalent, but argue that certain traditions, those surrounded by supernatural sanctions and sustained by coercive machinery, are the functional equivalent of law in 'primitive' societies.

Perspectives also vary in regard to how they frame the locus of traditional authority. One line of inquiry focuses on epistemological issues, emphasizing the binding force of traditional modes of thought, characterized by a purported resistance to or incapacity for rational, reflective, critical, or skeptical stances toward knowledge and belief. In a related vein, the emphasis may fall on the behavioral correlates of such epis-temological conservatism, manifested in traditional patterns of 'tried and true,' naturalized modes of action and in ritual. A third line maintains a discursive focus, concentrating

on authoritative discourse; here, authority is vested in the weight of ancestral and collective truth expressed in oft-repeated, socially resonant texts, such as proverbs, myths, or legends. Finally, we may identify a sociopolitical frame of reference, which is primarily concerned with traditional authority as vested in particular statuses or roles, such as elders (by virtue of their accumulated knowledge and the historical reach of their experience into the past) or ritual specialists (who control the coercive machinery of supernatural sanctions), whose claims to authority rest upon their connection to an authorizing past. These distinctions are analytical; much work, both theoretical and substantive, explores dimensions of interrelationship among these loci of traditional authority.

Tradition and the Construction of Modernity

The roots of the anthropological preoccupation with tradition lie in the seventeenth and eighteenth centuries, in the epistemological challenges of enlightenment empiricism, the religious overturning of the Protestant Reformation, and the interpretive explorations of classical and biblical philology. Enlightenment philosophers, such as Bacon and Locke in the UK and Condorcet in France, insisted that the rational, empirical pursuit of true knowledge required a throwing off of traditional authority, which demands the surrender of one's capacity for independent thought and renders one incapable of making new contributions to knowledge.

Baconian natural philosophy and the concomitant enlightenment ideology of progress were foundational to the development of antiquarianism in the late seventeenth and eighteenth centuries. Antiquities were the etiolated remnants of past ways of thinking, acting, and conveying knowledge that were 'derived down' uncritically into the present, shorn of their original meaning and functional coherence. In this sense, the notion of antiquities anticipates E. B. Tylor's concept of survivals. Only by rigorous historical investigation of their origins could they be fully revealed as irrational survivals of 'old customs' and expunged from modern life. For Protestant reformers, the remnants of old 'heathen' and 'Romish' 'superstitions,' handed down to the credulous members of the populace by 'custom,' 'tradition,' and 'hearsay,' were likewise to be revealed by historical investigation and extirpated from modern life. There was a clear sociological component to the antiquaries' and reformers' antiquarian programs as well, identifying the 'vulgar' classes, country people, the elderly, the uneducated, and women (as in 'old wives' tales') as the segments of the population among whom the survivals of past error were most likely to persist, thus, in effect, constructing a set of social 'Others' within contemporary society who were to be the special targets of tradition-oriented antiquarian investigation.

The development of eighteenth-century classical and biblical philology was stimulated by the literary battles of the Ancients and the Moderns, contesting the proper basis of contemporary literary production. This line of inquiry had a textual and interpretive focus: to render ancient and exotic texts, like the Homeric epics and the Hebrew Old Testament, intelligible, coherent, and meaningful to contemporary readers and to secure their canonical status and value. This interpretive approach combined a kind of protorelativism, reading the texts as shaped by the social, cultural, and linguistic milieu of ancient Greece or Israel – that is, as the inspired expressions of a nation – with a species of conjectural history, in terms of which the ancient texts were characteristic expressions of an early stage in the development of human society. One of the most significant methodological consequences of this approach was to motivate the use of data from living cultures – chiefly peoples of 'the Orient,' such as Arabs, Turks, East Indians – viewed as developmentally behind their modern European contemporaries, to illuminate the archaic cultures reflected in the Homeric epics and the Old Testament. These peoples of the East, then, took on the guise of exotic 'Others,' living exemplars of a 'rude' and 'primeval' age, bound by tradition rather than by an ideology of progress, reliant on oral communication rather than literacy, credulous and emotional rather than rational, and so on.

In a sweeping synthesis and extension of the philologists' program and a critical counterstatement to the social contract theories of enlightenment political philosophers, the German political philosopher, Johann Gottfried Herder argued that the authentic foundation of a viable polity is the poetic tradition of its people, made up of the inspired expressions of its poets – who are also its 'lawgivers' – who give voice to the spirit of the Volk, rooted in its particular time and place. This intertextually constituted tradition became 'the archive of the people,' the principal expression of national identity, the mechanism of its cultural cohesion and continuity, and the charter for its social and political life. In the most general sense of the term, Volk designates a nation, a people in its organic wholeness, but it may also designate that portion of a more complex, stratified society that remains grounded in its inherited language and traditions and still open to poetic feeling, as distinct from those who have been distanced from their traditions and feelings by over-rational refinement, the alienation of writing, or the adoption of foreign languages and alien ways. In Herder's (see Bauman and Briggs, 2000) intellectual synthesis, then, a precursor to Boasian anthropology, tradition is most powerfully operative in simpler, premodern, community-based societies and in those sectors of complex modern society in which a sense of community cohesion, the emotionally resonant ties of locality, kinship, and attunement to the national spirit still prevail.

Herder's thought was influential in the emergence of Romanticism, which was also inflected by the violent upheavals of the French Revolution. One response to the Revolution took the form of a conservative reaction, in which the sanctity of tradition and the cohesive force of kinship, religion, customary law, rootedness in place, and traditionally founded hierarchy were valorized as the essence of an authentic national character and a viable and moral polity. What is noteworthy, however, is that traditionalist conservatives tended to see the trajectory of change in the same terms as the rational reformers, framing an oppositional contrast between tradition and modernity. This contrast, convergent with jurisprudential investigations and symbolic constructions of 'customary law,' became the core of the classic typological tradition in social thought out of which emerged the modern social disciplines, including anthropology, in which the force of tradition served as a defining criterion of social types.

By the latter half of the nineteenth century, the foundational ideas we have summarized coalesced in a series of typological syntheses aimed at comprehending the broad historical trajectory of human social and cultural development and at providing a classificatory framework of social formations based upon stages of evolutionary progress. Whether framed in terms of ideal types, developmental continua, or evolutionary stages, these magisterial syntheses all accorded a defining or diagnostic role to tradition in the construction of contrastive social types. E. B. Tylor (1960 [1881]), for example, in contrasting 'savage' and 'civilized' man, ascribes the former's intellectual conservatism and aversion to change to his 'tendency … to consider his ancestors as having handed down to him the perfection of wisdom.' Ferdinand Tönnies (1988[1887]), in basing his classic distinction between Gemeinschaft and Gesellschaft on contrastive forms of common will, characterizes the 'natural will' that predominates in Gemeinschaft societies as becoming naturalized 'through practice and tradition.' Emile Durkheim, in outlining the contrast between mechanical and organic solidarity, attributes the authority of the collective conscience in mechanically solidarity societies to 'the authority of tradition.' Max Weber, in constructing his three pure types of legitimate domination, maintains that 'the validity of a social order by virtue of the sacredness of tradition is the oldest and most universal type of legitimacy.' These and related formulations served to crystallize the notion of 'traditional society' as a typological category, intellectually and behaviorally conservative, bound by an unreflective and unquestioning adherence to traditional ways and submission to traditional authority, and slow to change, in contrast to 'modern society,' dynamic, impelled by the exercise of reason and rationally motivated innovation, and open to change. This typological contrast has proven remarkably durable, persisting to the present day as an orienting framework in the social disciplines, not least in anthropology. *Mutatis mutandis,* it underlies Robert Redfield's folk-urban continuum, Karl Popper's closed versus open society, Talcott Parsons' pattern variables, Lévi-Strauss' cold vs. hot society, and a host of other variations on the theme, persisting in the face of trenchant criticisms of its resistance to operational specificity, its lack of analytical utility in the investigation of empirical cases, its masking of the dynamics of tradition in so-called 'modern' society, and its role in sustaining structures of social inequality and policies of domination.

Tradition in Contemporary Anthropology

The conceptual and critical reach of tradition in contemporary anthropology is pervasive, especially as it implicates the element of continuity in culture. We may, however, outline several foci of empirical, conceptual, and critical interest in which the notion of tradition figures relatively explicitly.

The Social Organization of Tradition

One prominent line of inquiry concentrates on what we might call the social organization of tradition, addressing those aspects of the typological model that cast traditional societies as homogeneous or undifferentiated, with the implication that tradition is collectively shared within the group. This understanding may be called into question in several ways, most directly by the recognition within the group of cultural specialists, who are charged with or have an individual bent toward the cultivation, formulation, or communication of tradition, as ritual specialists, elders, reciters, or other custodians of expert or esoteric knowledge. The foci of investigation here include the definition and organization of specialist roles; the recruitment, socialization and careers of cultural specialists; and the institutional and situational context in which cultural specialists act in their expert capacities.

This latter focus may direct attention to cultural performances or display events, such as rituals, festivals, contests, or dramatic performances in which the knowledge, symbols, and values of the group are embodied, enacted, and placed on public display. The production of such events typically requires the efforts of specialists in various capacities, and an organization of production by which the performance is accomplished. These lines of inquiry have been especially prominent in studies framed in terms of the distinction between the Great Tradition (cf 'high,' 'classic,' 'cultivated') and the Little Tradition (cf 'low,' 'folk,' 'popular') developed by Robert Redfield.

Investigation of the social organization of tradition may converge as well with the study of socialization and enculturation: the roles, contexts, and practices by which knowledge and behavioral patterns are conveyed to, and acquired by, succeeding generations. Finally, it is worth noting that the social organization of tradition has critical implications for anthropological method, insofar as cultural specialists figure prominently in ethnographic work as favored sources of data, and that ethnographic encounters, organized around the getting and giving of knowledge, are frequently framed as pedagogical events.

Tradition and Creativity

A further variation on the categorical opposition between tradition and modernity is the contrast between tradition and creativity, especially prominent in the anthropology of the arts. Classic work in this area, such as Franz Boas's *Primitive Art* (1955[1927]), tended to view tradition as a constraint on the 'primitive' artist, consistent with the typological conception of traditional society as inherently conservative and Herderian notions of artistic forms as the collective expression of a national spirit. Thus the convention of collective attribution that has dominated the presentation (with a few notable exceptions) of verbal and material art forms from 'primitive' or 'traditional,' or 'folk' societies (a Navajo chant, a French folktale, a Yoruba staff).

Since the 1960s, however, there has been an accelerating shift in the anthropology of the arts toward greater attention to the role of the individual artist/performer, and more nuanced investigation of the interplay between convention and creativity in artistic practice. In the anthropological study of the material arts, the distinctive styles and virtuosic achievements of individual artists and the situated practice of artistic production, use, and evaluation have aided significantly in the recalibration of the balance between tradition and creativity, and even further to a reevaluation of what constitutes creativity, no longer restricted to novelty but understood to include the use of conventional forms in new ways.

There has been a parallel development in the study of the verbal arts, stimulated by Milman Parry and Albert Lord's pioneering studies of the composition in performance of Serbo-Croatian oral epic and by the correlative turn to the ethnography of performance by linguistic anthropologists and folklorists. Central to these investigations is a focus on the situated nature of performance as a mode of communicative practice and recognition of the emergent quality of performance. In linguistic anthropology especially, the ethnography of performance has incorporated the close analysis of formal, functional, and intertextual relationships as a vantage point on the calibration in performance of conventional, 'traditional' orienting frameworks for the production and interpretation of discourse on the one hand, and the exigent and emergent 'creative' qualities of situated performance on the other. Both qualities are always present, and the task becomes one of determining the relative weight and the dynamics of interplay of the two in particular social and historical circumstances.

Tradition and Communicative Technologies

Closely related to the typological contrast between traditional and modern societies is the distinction between oral and literate societies, which foregrounds specific technologies of communication as diagnostic – even determinative – of the contrastive types. The typological uses of orality and literacy have their roots in eighteenth-century philology, which in turn had a shaping influence on anthropology. The twentieth century revival of this framework by classical scholars has once again infiltrated anthropology and re-energized debates concerning the validity of 'Great Divide' typologies. Stated in very general terms, the 'literacy hypothesis' attributes to the advent of writing, the invention of print technologies, and the associated spread of literacy, a concomitant transformation of modes of thought, specifically the objectification and decontextualization of knowledge, and the encouragement of a critical or skeptical orientation toward received truth. These intellectual (or cognitive) orientations, according to proponents of the literacy hypothesis, had a transformative influence on society and culture, effecting an epochal shift from a blind and unreflective adherence to traditional modes of thought and practice to the rational, scientific openness to change that is diagnostic of modernity.

While some anthropologists have endeavored to find ethnographic corroboration of the typological contrast between traditional and modern modes of thought, the weight of ethnographic evidence has tended to call the literacy hypothesis into question. The most effective and persuasive critiques have come from linguistic anthropology and related work in the anthropology of teaching and learning. A large and growing body of ethnographic studies, focusing on speaking, writing, reading, and the acquisition of communicative competence as social practices embedded in situational and institutional contexts of use, has provided a range of critical correctives to unitary conceptions of orality and literacy studied in relation to abstract systems of thought. These lines of research, illuminating the role of communicative technologies, forms, and practices in the production and reproduction of social life, offer as well an increasingly ramified and nuance understanding of the dynamics of continuity and change in human society, to supplant the classic categorical distinction between tradition and modernity.

The Politics of Tradition

The political force of tradition has been a consistent theme in anthropology, built into the very foundations of the discipline and epitomized in Weber's identification of traditional authority as one of the three pure types of legitimate domination. Oriented by classic conceptions of traditional authority and 'traditional' society more generally, foundational studies of traditional authority in anthropology have tended largely to view it as a unifying force in the service of social system maintenance, sustained by the mechanisms of socialization, the mythological charter of institutions, and the rigid formalization of ritual and traditional oratory.

Here again, however, the ethnographic turn to situated practice, and especially to discursive interaction and performance, has led to recognition of the ways that traditional tales, for example, may be instruments of divisiveness rather than unity, insofar as they may be performed in defense of competing claims to status, or that the formal regimentation that marks the performance of oratory as 'the words of the ancestors' may serve to enhance the rhetorical power of disputants in political conflict. That is to say that rhetorical appeals to tradition and the public ideologies of traditional authority that motivate them do not necessarily have the binding force in practice that participants and observers alike may claim for them. Ideologies of traditional authority – like all ideologies – are positioned, interested, and strategically invoked, and tradition as a rhetorical resource may serve as well for conflict as for the 'binding force' of acquiescence.

The ideology and rhetoric of tradition are understandably more apparent under conditions of marked social and cultural change; indeed, the capacity of 'traditional' peoples consciously to intervene in the management of tradition was recognized earliest in anthropology in the study of nativistic movements, 'any conscious, organized attempt on the part of a society's members to revive or perpetuate selected aspects of its culture.' (see Linton, 1943) This work anticipated a vigorous line of anthropological inquiry that has burgeoned since the 1980s, devoted to the investigation of tradition and related notions of authenticity as symbolic, interpretive constructions in and of the present through the invocation of links to a meaningful past.

The process of traditionalization – under the rubric of tradition, heritage, patrimony, custom, or the like – is a prominent resource in the service of nationalism, whether cultural nationalism or nation-state formation, and it is a conspicuous aspect of the politics of culture in many parts of the world in which there is an extended history of anthropological research but which are now increasingly determined to shed the vestiges of a colonial past and assert the integrity and authenticity of their own 'cultural traditions.' The readiness of anthropologists to identify the tradition or custom, or patrimony on which such claims stand as selective, strategic, symbolic constructions is a source of tension both within the discipline and between anthropologists and their ethnographic interlocutors: whose interpretations and constructions are to be accepted as authoritative?

This question and the further problems it raises afford an illuminating critical vantagepoint on the historical formation of anthropological theory and practice. The modern conception of tradition was shaped in an intellectual arena that was defined largely in political terms. What are the foundations of a viable polity? A legitimate authority? A national culture? What are the bases of social inequality? Who is authorized to intervene in the management of these formations? Tradition and allied conceptions of culture proved to be foundational to the emergent discipline of anthropology and the definition of its purview. A measure of the success of anthropology may be strength with which its core concepts have come to be accepted by the formerly 'traditional' peoples who have been its central objects of study. One of the challenges that now confronts anthropology is that in asserting their own subjectivity, these peoples should base their claims on those foundational concepts just as anthropologists themselves are increasingly inclined to deconstruct them, to recognize traditionalization as an interpretive process, to challenge the reification of tradition, or to unmask primordial traditions as recent inventions.

Abstract

Contemporary sociology considers tradition as an invented reference developed in function of the demands of the present and as a form of rationality among others that orients action. To be part of a tradition, objects, norms, or ideas have to be *living* in the sense of never having been forgotten. Tradition is a transformed heritage which survives and orients contemporary actions as seen in many fields of empirical research. The market consumption society offers standardized products but cultural diversity continues to be reaffirmed by living cultural traditions. New technologies have a great impact on the character of work, but work is also embedded in culture and traditions.

While the concept of tradition has been important in sociological thought since the foundation of the discipline, its signification has completely changed in contemporary works. At the turn of the twentieth century, sociologists and anthropologists utilized this concept to outline a type of society defined by certain traits placed in opposition to the traits characterizing industrial society, and in a well-known work Max Weber distinguished three types of authority: legal-rational, charismatic, and traditional. One hundred years later, sociology considers tradition as an invented reference developed by societies in function of the demands of the present (Hobsbawm and Ranger, 2012) and as a form of rationality among others that orients action (Boudon, 1992).

The tradition–modernity dichotomy dates back to Saint-Simon who compared the characteristics of the emerging industrial society to those of the *Ancien régime*. This dichotomy became a key element in explaining the social transformations that were occurring in modernizing societies during the first part of the twentieth century. The defining traits of the traditional society are well known: the fusion of family and business, the division of labor dictated by social structure (age, gender, relatives), reference to customs as the dominant value, the privileged attention accorded to saving and accumulation to the detriment of productive investment, the importance of the local community, relative autarky, and self-reliance. In a work that has been read by generations of American students and remains a classic in the social sciences to this day, the American anthropologist Horace Miner (1939) found a kind of archetype of preindustrial traditional rural life in Saint-Denis-de-Kamouraska, Quebec. At the opposite end of the spectrum, the industrial society described by Raymond Aron, Georges Friedman, Daniel Bell, Krishan Kumar, and others is marked by the growing importance of technology, economic growth, calculation, and management, productive investment and the accumulation of capital, the separation of family and business, the establishment of a labor market, and urbanization.

The transition from traditional to industrial society paradigm and the folk–urban continuum formalized by Redfield (1956) were criticized by some authors as descriptive approaches of social change and as paradigms of limited explanatory power. Henri Mendras (1976) argued that these perspectives did not recognize the proper originality of nonindustrial societies as well as their diversity. Furthermore, as a concept, traditional society is used to refer to several types of societies that are in fact very different from each other (e.g., primitive societies and peasant societies) and one should not confuse them. If hunter–gatherer societies are totally independent, peasant societies are relatively autonomous but embedded in larger, global societies having more diverse characteristics. The paradigm of the transition from traditional to industrial society is based upon an evolutionist postulate (heavily criticized) that claims developed societies constitute the norm to thrive for. In the same vein, we can criticize the thesis of the resistance to social change by tradition because it supposes clear, obtainable goals and also the existence of bad faith on the part of traditional individuals attached to the past and incapable of recognizing the merits of anything new (Boudon, 2007).

Consider another manner of conceptualizing the opposition between the traditional and the modern. Levi-Strauss (1962) compares the knowledge and technique of the handyman, which are traits of traditional society, with the knowledge and technique of the engineer, which are attributes of industrial society. The first type of knowledge is empirical and inductive. It relies upon a long tradition of precision which can be complex and efficient but it is also filled with errors, notably as to the explanation of its efficiency. The knowledge of the engineer is of a different order. This type is based upon experimental science, the accumulation of scientific knowledge, verification, technology, the manipulation of objects, operationalization, and organization. The classical opposition in economics between protectionism and free trade also illustrates the opposition between the ancestral or traditional ways of doing business and the modern methods. The authorities in the Republic of Venice jealously protected the ancestral traditions of their glass makers, sources of important benefits. Contemporary entrepreneurs on the other hand count on innovation, discovery, free circulation, investment, and strategic alliances to support the growth of their activities and profits.

The examples of the engineer and the entrepreneur clearly demonstrate that tradition and modernization are differentiated in two respects. First, the relationship to time is different. Tradition is oriented toward a legitimate reference to the past while modernization is oriented toward the mastery of the

future, the discovery of the new. Second, tradition and modernization are marked by a strongly different manner of intervening in the world, of producing goods and services; an empirical manner of learning over time and transmission across social relations that are embedded within the family or small communities, and a scientific manner that asserts itself as the result of research and calculation, embedded within complex social networks and formal organizations.

Shils (1981) proposed a definition of the concept of tradition that was largely accepted. He defined tradition as anything that is transmitted or handed down from the past to the present. Traditions include beliefs, norms, institutions, as well as material objects which all individuals will find when they grow up; traditions refer to transmitted things, ideas, values. It is now generally accepted that the scope of tradition should be narrowed down. We will retain two aspects – which are hidden in the folk–urban continuum or in the community-society ideal type of Tonnies – which contribute to define tradition in contemporary analyses.

First, to be part of a tradition, objects, norms, or ideas have to be *living* in the sense of never having been destroyed, abandoned, or forgotten. Specifically qualified fragments of the heritage must maintain a strong intimate link with the present to remain a tradition. Second, it is generally accepted that traditions change with the passage of time. While traditions are often thought of as immutable and fixed, they are subject to be reexamined and questioned through the passage of time (Dumont, 1968). Tradition is a transmitted heritage which survives and orients contemporary actions, but this heritage is often transformed (Halbwachs, 1994/1936; Eisenstadt, 1973; Sylvestre, 2012). In this regard, Sztompka (1993) stated that a special part from the whole of the historical heritage is elevated to the status of tradition by contemporary people for their own usage. From time to time, nations are re-founded on a new basis in order to recognize and incorporate emerging elements, for example, a growing proportion of immigrants (Dumont, 1993; Taylor, 1989). In the United States, national history is being rewritten to take into account the role of the indigenous peoples, women, and ethnic minorities. Accordingly, Michael Lind (1995) distinguished four types of 'American nations': Anglo-America, Euro-America, multicultural America, and finally, 'the new American ethnicity.'

In 1998, the Canadian government established a new territory populated by an Inuit majority – Nunavut – that took into account the testimonies of the oral traditions of the elders. Scientific cartography and satellite images were the privileged work instruments but the life histories and experiences of those who inhabited the land were taken into account, especially to establish its Eastern frontier. Similarly, the oral traditions of Canadian Aboriginals and the wampums of their material culture were also taken into account as elements of proof in the Canadian system of justice that examined their grievances and their ancestral rights. Canadian judges are now obliged to interpret the rights of Aboriginal people in light of ancestral traditions, on one side, and the orientations of modern ways of living (equality between men and women, for example). The resort to tradition inspires other courts of justice throughout the world where we find indigenous cultures, in Latin America or in Oceania, for example. Here, tradition appears also as a legitimate form of knowledge, but different than the scientific knowledge and cartographic techniques of historians or jurists, and it is susceptible to applications in the same way as the latter. Tradition no longer appears as the only principal source that orients behavior and decisions but as one element among others that is susceptible to being criticized.

Hobsbawm and Ranger (2012) have contributed to the new perspectives on tradition by stressing its invented character. They have distinguished three groups of invented characteristics. First, there are traditions which express the social cohesion of nations and communities. Second, traditions can legitimize existing order, status, institutions, or authority. Third, traditions socialize individuals to certain values or rules of behavior. The traditions of the British crown, for example, leave the impression that they are rooted deep into the past. The work of historians has now demonstrated that these traditions are of more recent origins and were invented quite recently (in fact in the nineteenth century) in order to give greater legitimacy to the institution of the monarchy. The celebration of the new Beaujolais in France is a recent creation, the fruit of a new approach in the marketing of the wine of this region that has been successful in countries where they appreciate French wines. Another example, some Australians and Canadians have questioned whether or not their country should abandon the royal symbols from their colonial period. Abandoning those traditions and symbols would probably oblige them to invent other symbolic tradition to mark the birth of their society peopled in large part by immigrants. A new tradition would, therefore, be created for use in the present.

The protection of the environment, fauna and flora, became a daily theme at the end of the twentieth century. In North America, the Aboriginals have been characterized as environmentalists before the advent of the environmental movement. Research by anthropologists and historians has demonstrated that the reality is much more complex. Krech (2000) recalls that Aboriginals had overexploited the beaver in the St. Lawrence Valley to the point of extinction after the arrival of Europeans in sixteenth century New France. The notions of environmental protection and endangered animals were foreign to the traditional culture of the Aboriginals, because the way of life of hunter-gatherers is based upon the maximal exploitation of the immediate environment. On the other hand, Aboriginals have an animist conception of the animal world. Thus, the Plains Indians believed that they could not allow an animal to escape under the pretext that it would warn the others to not venture in that area, they therefore killed all the animals they saw. Because they believed in reincarnation, the majority of Aboriginals thought that the dead animals would, at any rate, return the following season. For Krech, the myth of the ecologist Indian essentially reflects contemporary preoccupations for the environment rather than the traditional and historical culture of the indigenous peoples.

This analysis leads us to the following conclusion: sociology has abandoned the transition paradigm (from traditional to industrial societies) and integrates tradition into analyses of ongoing social change. Tradition is used to define a type of society (be it theoretical or empirical), and it also defines a subjective orientation toward action. We will further discuss these different approaches.

In his general theory of action, Freitag (1986) defines different types of societies based on forms of definition of the norms of social action. The first form he proposes – culture – defines mythic and archaic societies. The second one – power – defines two other types of societies: traditional societies and modern societies, the later ones built against tradition. The third form of regulation – control – characterizes postmodern society, in which a large number of organizations contribute to the structuration of society.

Tradition is also used to describe empirically different societies. Huntington (1996) argued that the world is divided into eight major cultural zones which reveal persistent cultural differences caused by different religious traditions which are still powerful despite industrialization and the same forces of economic development. Inglehart and Baker (2000) studied values by surveys made in 65 countries which cover more than 75% of the world population and they observed the persistence of distinctive traditional values.

In contemporary sociology, tradition is considered as a normative orientation toward action, a perspective underlying Tocqueville's books (1856, for example). In his works, Raymond Boudon (1992) formulates a general theory of action based upon the actor's search for meaning. He proposes to enlarge the concept of the rationality of the actor by distinguishing five types of rationality: utilitarian, teleological, axiological, cognitive, and traditional. All of these types of rationality describe the good reasons why the actor is driven to act in a certain way. Economists and rational choice theorists privilege the utilitarian rationality based upon the pursuit of self-interest. However, for Boudon, there are other kinds of reasons/motives that can also influence the way individuals act, and limiting the concept of rationality to the single dimension of utility is an exercise in reductionism. Custom and habit can also incite individuals to act in a certain way. Therefore, when one speaks of traditional rationality – "it has always been that way" – he or she is speaking of one type of rationality among others.

Sociological analysis has to define the context and circumstances in which one type of rationality or another is at work, keeping in mind that one type is no more important than another. This approach permits us to understand the role of tradition in sociological explanations. In peasant societies, the rhythm of the seasons is of major importance and technology is not very advanced (Weber, 1976). Here, the reference to custom and tradition is strong and individuals do not have good reasons to question what already works. They are led to value stability and the family that provides the necessary labor to exploit the land. However, when technological inventions appear to menace the traditional ways of life, tradition remains important for understanding the implantation of these transformations or the difficulties in accepting them. The introduction of inventions in peasant societies cannot be understood independently of the host culture because these innovations have to be first integrated into the traditional culture before being fully accepted.

The celebrated monograph by Thomas and Znaniecki (1984) on immigrant Polish peasants in Chicago gives a good example of the role of tradition in ongoing social change at the turn of the twentieth century. The immigrants that adapted the most rapidly to the host society were those that manifested the highest degree of traditionalism and attachment to their original milieu. This integration in a familiar milieu gave them support and a frame of reference that slowed down the process of social disorganization that was typical of immigrant communities when faced with a radical rupture with their traditional original community. The Polish immigrants adopted a rational action that allowed them to integrate to their new society with the traditional collectivity serving as a relay.

To illustrate the richness of this approach, here is an example taken this time from French sociology. In his studies of religious sociology, Le Bras (1955) observed the following paradox. The deeply religious Bretons who migrated to Paris in the 1950s rapidly stopped practicing their religion. A superficial analysis gave the impression that they had simply abandoned a strict and conformist religion as soon as they found themselves away from the traditional village life. Le Bras proposed another explanation by demonstrating that the underlying logic of behavior was the same in the village and in the city. In the village, behavior was regulated by the social group. Going to mass was not only a way of practicing one's faith, it was also participating in a valued social activity which strongly regulated village life. In the city, a pluralist environment, going to mass was seen as expressing an opinion and a behavior that did not attract the adherence of all, and in a way, that was contrary to majority opinion. Thus, it was difficult for the newcomers, who wished to integrate to their new environment, to oppose something which was the norm in their original milieu. In this case, one could say that going to mass in the village and not going once in the city follow the same social logic.

All of these examples point out different ways to refer to the concept of tradition. Tradition describes a type of society but it also defines an orientation of action. This perspective can be found in numerous works of contemporary sociology and demonstrates how different types of rational behavior can syncretize. To illustrate this perspective, we will recall how the reference to tradition is posed in three major fields of empirical research.

The market consumption society in the developed world offered standardized products – fast food, coca-cola, computers, cars, jeans, CDs, films – and globalization tends to homogenize commercial practices and modes of production. However, sociologists have observed the multitude of innovative responses in the national cultures of consumption and have noted that local contexts remain extremely diversified and, in each case, outside material influences are reinterpreted. Cultural diversity continues to be reaffirmed and supported by living national and cultural traditions. Coca-cola does not occupy the same place in the dietary culture of the French and the connoisseurs know that American pizza is quite distant from its Italian cousin (Ritzer, 2006). New technologies have a great impact on the character of work, but work is also embedded in culture and traditions. People work, and supervise other's work, within stringent institutional limits marked by both national traditions and organizational innovation.

The empirical work on the integration of immigrants in developed societies demonstrates that they do not form totalities with contours that are well defined by their original traditions. In fact, they are quite diverse and in reconstructing their traditions in the new country, they combine innovative

elements with the adopted elements of their new home. Tradition and modernity combine to produce new cosmopolitan identities that can be different from one country to another as Kymlicka (1995) suggested. The reference to tradition, therefore, remains quite alive in sociological analyses.

Trafficking of Women and Children in Latin America

Mirna E Carranza, School of Social Work, McMaster University, Hamilton, ON, Canada

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article summarizes emergent themes related to social work and the trafficking of women and children in Latin America. A literature review revealed that empirical and scholarly work in this field is very limited, so a systematization of the literature – in English and Spanish, including internal community and organizational reports – is introduced here. Key themes include the recruitment, purpose(s), risk factors, consequences of trafficking on survivors' health, barriers to addressing trafficking, and the role of social work in this area. Women and children in Central America appear to be at particularly high risk due to geopolitical, historic, and economic issues.

Introduction

Human trafficking is a pervasive global social phenomenon and is a multimillion dollar business (Estés and Weiner, 2003). According to the United Nations Children's Fund (UNICEF), 1.2 million children are trafficked every year (UNICEF-Child Protection, 2010). In 2000, the United Nations (UN) introduced two optional protocols to the UN Convention on the Rights of the Child to address some of the worst forms of human rights abuses perpetrated against children and women globally, including sex trafficking. The protocols prohibit the sale of children, child prostitution, and child pornography; require that a state's criminal or penal law regulate particular banned acts; set forth various methods for enforcing jurisdiction and extradition; and specify the protection of children victimized by the prohibited practices (Revaz, 2009). To date, 18 of 23 Latin American countries have signed or ratified such protocol (Guinn, 2008). Signing countries have developed legislation, public policies, and preventive strategies to deal with this social issue.

Trafficking of women and children is very difficult to detect and quantify because of its underground nature (CONAPINA, 2002). Therefore, numbers and statistics are often estimated (Wolf-Branigin et al., 2010). Most of the available data come from institutional reports. To date, little research has focused on the nature and extent of trafficking of women and children in Latin America (Sumner et al., 2004), but nongovernment organizations (NGOs) and human rights advocates report that Latin American women and children continue to be subjected to violence, abuse, and trafficking for the purpose of commercial sexual exploitation (CSE) (Scarpa, 2005). From 2007 to 2010, an estimated 6000 individuals were trafficked in Latin America: 1600 (27%) children and 4400 (73%) adults, almost entirely women (UNODC, 2012). In Latin America, the trafficking of children and women is rooted in its history of colonization. Women, especially Indigenous and African women, have been trafficked for the purposes of: (1) providing free labor, (2) bearing more slaves, and (3) sexual objectification (Chiarotti, 2003). Research also indicates that this region is currently a destination for accessing trafficked women and children (Phinney, 2001). According to the Human Rights Watch (HRW), weak government institutions, the absence of a formal regional legal framework for penal, economic, and financial interventions (2012), and a lack of political endorsement and/or commitment to addressing this complex issue make Latin America fertile ground for human trafficking (III-LACHT, 2012).

Recruitment and Trafficking

Recruiters use various techniques to bring women and children into the sex trade: kidnapping, bondage, deceit about possible employment, fraud, fear, physical violence, confiscation of travel documents, forced substance use, threats of violence toward family and friends, debt, and threatened deportation (Potocky, 2010). Recruiters are often family members or friends of victims, and many traffickers are women (Azola, 2001). A recent study conducted in the Dominican Republic (Carranza et al., 2010) reported that children who are forced to grow up in this type of environment are used as recruiters when they become older (17–19 years). They befriend younger children, gain their trust, and convince them to join what appears to be a 'fun' life. Another study conducted in Nicaragua (Carranza et al., 2011a) reported that children and young women are recruited for CSE within schools in impoverished communities. The Latin American region is very distinct in which 50% of the individuals prosecuted for human trafficking are women (UNODC, 2012). However, in this region, "women who are prosecuted for trafficking in persons are less likely than men to be convicted in comparison with Eastern Europe and Central Asia" (UNODC, 2012: 61–62). The reasons for this require further exploration.

Trafficking in Humans: For What Purpose?

According to the United Nations Office on Drugs and Crimes' (UNODC, 2012) report on global human trafficking, 51% of the trafficking in Latin America is for the purposes of sexual exploitation, with forced labor a close second at 44%. 'Sexual exploitation' includes: (1) child prostitution, (2) pornography, and (3) sex tourism (Covenant House, 2001). Other reasons for trafficking may include: (1) to be part of a militia, (2) forced marriage, (3) organ harvesting, and (4) illegal adoptions (UNODC, 2012).

Forced labor can be considered a particular form of slavery that is difficult to identify and estimate. It uses a different criminal network from that of sex trafficking, and instead involves involuntary servitude through coerced household,

 http://dx.doi.org/10.1016/B978-0-08-097086-8.28114-2

factory, or fieldwork (TIP, 2009). According to Molina (2008), trafficked women and children may also be involved in the entertainment business and/or drug industry, e.g., they may be used as 'mules' to transport drugs across borders. These individuals often risk their lives by ingesting drugs to avoid detection by border security. A recent study conducted in the Dominican Republic (UNICEF-Dominican Republic, forthcoming) reported that Haitian children and adolescents migrating alone to the Dominican Republic are at great risk of being captured by traffickers. Traffickers force boys to beg on the streets, and force girls to work as maids. A growing transnational and underground network is involved in moving women and children from place to place (Fontela, 2007), and in 2010, UNODC reported that of the 140 000 individuals trafficked to Western and Central Europe for sexual exploitation, 13% were from Latin America.

Conflict reproduces distinctive kinds of power relations (Bukachi et al., 2010). Recruitment of young women and children into militias is common in countries in political turmoil (Escorcia, 2007), including El Salvador, Guatemala, and Colombia. According to the HRW (2012), the Fuerzas Armadas de Colombia has reportedly kidnapped children for use as child soldiers. Molina (2008) added that more than 2500 Venezuelan children have been abducted to fight in the Colombian war.

Other purposes for trafficking children and women include forced marriages or servitude. Captors often confiscate documents and force victims to commit petty crimes under the threat of reporting them to the police if they disobey (Chiarotti, 2003). Organ harvesting is another common reason for human trafficking. Reports of missing women and children are often dismissed by authorities, who assume the individual has simply run away, so family members are often left to search for their loved ones alone (Molina, 2008).

In Latin America, the trafficking of children for the purpose of illegal adoption is a US$20 million per year industry, and children in Honduras, El Salvador, Ecuador, Venezuela, and Guatemala appear to be most at risk (Molina, 2008). According to a 2000 United Nations Economic and Social Council report, Guatemala is the fourth largest exporter of babies worldwide; the report also describes how mothers are tricked, paid, or robbed of their children.

Risk Factors

Most of the factors associated with trafficking of women and children for the purpose of CSE in the Latin American region are similar to those in the rest of the world: economic disparities, gender violence, and gender discrimination (Pop, 2012). Geography, class, and ethnicity are also important factors: Indigenous women from Amazonian and rural communities (Kempadoo, 2007), and Black Caribbean women (Bullock, 2010) are highly sought out and marketed to Caucasian males using colonial and racist descriptors such as 'dependent,' 'erotic,' and 'sex-crazed' (Bullock, 2010). A study conducted in the Dominican Republic reported that customers from European and North American countries particularly seek Black children and women, but prefer them to be well-groomed (i.e., clean, good teeth, well-groomed feet, straight hair; see Carranza et al., 2010).

The trafficking of women and children is a manifestation of gender violence (Robles and Pérez, 2012) and is the ultimate act of domination, both sexual and economic, over its victims (Aguilar Pérez, 2009). It is rooted in patriarchy and masculine gender ideology (Acharya, 2009), in which gender relationships are socially constructed (see e.g., Godoy, 2013). Societal attitudes (Gómez and García, 2006) of gender exclusion and violence underpin the violation of human dignity against women and children (Covenant House, 2004). However, the general population in Latin America tends to take these acts for granted as part of the 'natural world' (Centeno, 2006).

Researchers have identified other specific vulnerabilities in Latin America, including gang affiliation, ongoing substance abuse issues, having children before the age of 18 (Sumner et al., 2004), political instability (Phinney, 2001), and migration (Covenant House, 2001, 2004). Carranza (2012) found that children whose parents have migrated tend to experience isolation, abandonment, nonbelonging, and social stigma. They also tend to grow up with less supervision, and are therefore highly vulnerable to being recruited for CSE.

Childhood sexual abuse and intrafamilial violence reportedly play a significant role in the trafficking of women and children for the purpose of CSE (Martínez-Sotelo and Zúñiga, 2007; Roby, 2005). A study conducted in Nicaragua (Proyecto Miriam, 2008) reported that of 83 participants who had endured child CSE, 28% were survivors of sexual assault as children prior to entering the sex trade. Estés and Weiner (2001) studied three countries (Mexico, the US, and Canada) and found that most of the children involved in the sex trade had previously been exposed to childhood sexual abuse.

Central America: A Unique Region

Central America is a unique region in terms of trafficking women and children for CSE. Of its 41.3 million residents, approximately 33 million live in poverty due to historical influences (Solís and Solano, 2001). Its geopolitical position has been linked with organized delinquency (Heinemann and Verner, 2006), drug trafficking (Call, 2000), and trafficking in persons for sexual exploitation (ILO, 2009).

A 2002 study by the International Human Rights Law Institute of Central America reported that trafficking women and children for CSE is widespread in the region and occurs both internally (from poorer to wealthier or more developed areas) and across international borders. Internal trafficking is common in Guatemala, Honduras, and the Dominican Republic, with women and children trafficked from rural villages to tourist destinations along the coast. Crimes related to CSE are not generally considered illegal by either state institutions or citizens; rather, they are understood as part and parcel of transnational organized crime (Save the Children, 2011). Together, these illegal activities have eroded the social fabric, generated private and public corruption, and intensified institutional fragility.

In Central America, most victims of CSE are moved from Honduras to Guatemala (TIP, 2012). Nicaragua also receives trafficking inflows from South America and is a point of origin for traffic flowing south (Costa Rica) and north (Honduras).

The Free Transit Agreement among Nicaragua, Honduras, El Salvador, and Guatemala has strengthened the international route toward Northern countries (i.e., Canada and the US; see Acharya, 2009).

Consequences of Human Trafficking on Children and Women

Children and women survivors of sex trafficking endure life-threatening health consequences (Sexually transmitted diseases, HIV/AIDS, unwanted pregnancies), trauma (see Carranza et al., 2011a), and chemical dependency, which prevent them from achieving optimum mental and social well-being (UNFPA, 2007). Furthermore, when survivors of human trafficking attempt to access the judicial system in search of recognition and/or validation of the crimes committed against them, they are often met with acts and omissions aimed at delaying, preventing, or persuading them against exercising their human right to justice (Flores Chang, 2007). Furthermore, lack of education and poor health (Chiarotti, 2003), coupled with unemployable skills, weaken the social integration of women and children who have been subjected to trafficking (Martínez-Sotelo and Zúñiga, 2007). Children, in particular, face discrimination as they attempt to reintegrate with schools, friends, and communities of origin (Carranza et al., 2010). Political issues of repatriation continue, as victims of trafficking are often enmeshed in political bureaucracy (Carranza et al., 2011b). With a few exceptions, holistic initiatives related to prevention, intervention, and/or reparation are scarce (see Arredondo, 2011 for Chile; García, 2012 for the Dominican Republic). It is vital to develop spaces and trained personnel to support women and children who have endured trafficking.

Barriers to Addressing Human Trafficking

A major challenge related to addressing the trafficking of women and children is the 'invisibility' of perpetrators. For example, South American tabloids often portray police forces raiding brothels and nightclubs, detaining women and children who have been sexually exploited, rather than focusing on the traffickers (Rodríguez, 1999). Although the focus should be on the demand for CSE and the perpetrators of CSE, blame tends to fall on victims (Chiarotti, 2003).

The demand for CSE in Latin America is increasingly global (Altman, 2001). Hence a critical examination of how global forces intersect with local realities is necessary to clarify the actors and power dynamics involved in CSE (Carranza and Parada, 2010). In a qualitative study conducted in the Dominican Republic, Carranza et al. (2010) found that national Dominicans are perpetrators of CSE, but Asian, European, and North Americans (the US and Canada) tend to be the major consumers. In another study, Carranza et al.(2011c) found that women and children along Nicaragua's Atlantic Coast are particularly vulnerable to CSE from cargo ships' crew arriving from North American, Asia, and Europe, and from truck drivers moving cargo across the borders in Costa Rica and Honduras. They also found that in Granada, European men openly parade with a female child on their arm (Carranza et al., 2011b).

These crimes frequently go unpunished due to the silence of the civil population and corruption of government officials at all levels (Aguilar, 2009). The International Labour Organisation (2005, 2009) found that public acceptance of trafficking and sexual exploitation of women and children increased between 2005 and 2009. UNICEF (2005) found that many accusations made, to perpetrators of trafficking and/or CSE, by survivors or bystanders are dismissed as false. A recent study conducted in the Dominican Republic (Carranza et al., 2010) reported that children were being subjected to CSE mostly in tourist areas. However, this social issue is rapidly expanding to other public places such as shopping malls strongly suggesting that CSE is becoming more accepted throughout all segments of society and not just relegated to tourist areas. In another qualitative study conducted in Nicaragua (Carranza et al., 2011b), the participants noted that public apathy can actually protect survivors and their families by keeping them out of the legal system; the judicial system tends to revictimize survivors by attacking their character rather than focusing on perpetrators. This particular study also found that despite the work of human rights and child advocates, the demand in Granada, Nicaragua is so powerful that sexual relations between White men and local children are being constructed as 'normal relations' and part of the entitlement of White men.

Besides public apathy, perhaps the biggest challenge in addressing the trafficking of women and children for CSE is the lack of trust in authorities (i.e., police, government). A government's role is to represent and protect its citizens, particularly vulnerable groups, but women and children who have been trafficked report that they cannot trust authorities to assist them (Amar, 2009). According to participants in recent studies (Carranza et al., 2010 for the Dominican Republic; Carranza et al., 2011b for Nicaragua), most cases of trafficking of women and children involve government officials and police as consumers and direct beneficiaries, as they often accept bribes to ignore illicit activities and not pursue and prosecute individuals accused of these types of crimes. Thus, participants not only reported fear of reprisals from perpetrators, but indicated that reporting CSE is a waste of time because the authorities are often involved in the phenomenon.

The Role of Social Work

A few social work interventions have focused on CSE in Latin America, as in most Latin American countries the articulation of social work and CSE is emerging – i.e., Colombia (Mendez Villamizar et al., 2011), and other Caribbean (see Parade et al., 2007 for Dominican Republic), and Central American countries (see Carranza et al., 2011a,b,c for Nicaragua). Although Musto and Trajtenberg (2011) noted the lack of social work research in this particular area, social work is being actively conducted in several countries (e.g., Brazil, Argentina, Costa Rica, Chile). Social workers tend to work alongside other professions to address CSE but, according to the III Latin American Congress on Human Trafficking (2012), regional initiatives undertaken by academics, NGOs,

and the private sector are still in the early stages of raising awareness about CSE and understanding, preventing, and penalizing it. Interventions may include harm reduction, with victim-centered holistic approaches focusing on basic needs (e.g., food, shelter, clothing). Human rights activists continue to advocate for health care, counseling, education, and legal rights (Androff, 2010). Pressure by international NGOs and human rights activists has also increased the perception of human trafficking as a crime against humanity (e.g., Covenant House, Salvation Army, Save the Children). Laypersons and professionals (sociologists, teachers, lawyers) have been charged with performing interventions related to CSE, so international NGOs (Save the Children, UNICEF) have been involved in providing competency training for local employees working with the victims of trafficking (Guajardo, 2010).

Professional Social work in Latin America faces many challenges that impede worker's ability to effectively address CSE. Some countries, for example, still face the legitimation of the profession (e.g., Dominican Republic) and consequent limited funding (Sevilla, 2006); in other countries, social work has been marginalized due to its involvement in revolutionary and resistance movements (e.g., El Salvador, Honduras, Guatemala, and Chile). Social workers have been persecuted, tortured, or 'disappeared' throughout decades of government repression. In some cases they continue to be a watched group from the perspective of oppressive governments, which severely limits their ability to respond to or prevent CSE.

Conclusions

This article has identified several important challenges related to CSE in Latin America: (1) the complex issue of the trafficking of women and children is not fully understood, (2) only few preventive strategies have been designed to address this problem, (3) no guarantees are available to ensure that the human rights of victims are protected in relation to accessing justice; (4) perpetrators and traffickers are invisibilized as legal actions remain underdeveloped; and (5) aid and service provision for survivors of CSE is limited. CSE tends to be labeled and treated only in terms of 'woman and/or child abuse,' thereby contributing to its invisibility and to the revictimization of women and children that have endured trafficking if they disclose.

At the core of human trafficking – particularly of children and women – is the failure to recognize that children are entitled to human rights, and the denial of basic human rights for women. The trafficking of women and children within the Latin American region is closely linked with sociocultural and historic tenants including gender inequality, gender violence, social exclusion, expressions of masculinity, discrimination, and prejudice.

The role of the international community is pivotal. Involvement by the UN and international NGOs is crucial, as their 'international' status provides them with the authority and power to pressure government officials to address CSE. Moreover, international social workers play a pivotal role by providing technical support to social workers working with survivors of CSE. Reliable and ethical research protocols and social work practices are imperative. Moreover, the trafficking of women and children for the purpose of CSE must be included in academic curricula and research programs for social workers.

Training in Clinical Psychology in the United States: Practitioner Model

Roger L Peterson, Antioch University New England, Keene, NH, USA

Abstract

The National Council of Schools and Programs of Professional Psychology's practitioner-scholar model for education and training in professional psychology appeared in 1997 and 2010 (Peterson et al.) with five central components. Many elements of the five components are updated from their original presentations: (1) broadened view of psychology with a flexible epistemology, multiple ways of knowing, and an articulation of how practitioners doing practice remain 'local clinical scientists' doing 'disciplined inquiry'; (2) integrative pedagogy; (3) competency-based core curriculum integrating practical and scientific knowledge, skills, and attitudes, now including diversity; (4) elements of practice, including multiple roles, the self of the psychologist and reflective practice, practicum and internship training, and systematic evaluation; and (5) the social nature of professional psychology and its social responsibility, including an appreciation of ethnic and racial diversity, and gender. The impetus for the practitioner-scholar model and the critiques of the professional psychology movement are briefly mentioned.

The practitioner-scholar model of professional psychology education along with the scientist-practitioner model and the clinical scientist model are the three most influential models in doctoral-level professional psychology education. This summary of the practitioner-scholar model abbreviates the Peterson et al. (2010) version, which itself updated the Peterson et al. (1997) National Council of Schools and Programs of Professional Psychology (NCSPP; see NCSPP.info).

Founded in 1976, NCSPP is an organization of professional schools and programs in psychology whose central mission is the progressive improvement, enhancement, and enrichment of professional psychology education and training. In 2012, NCSPP consisted of 66 members with full accreditation by the American Psychological Association (APA) and 20 associate members who were at various stages of the accreditation process. The description of NCSPP's model is consistent with the requirement by APA's Committee on Accreditation (APA Office of Program Consultation and Accreditation, 2011) that programs identify an educational model that has a "clearly specified philosophy of education and training…appropriate to the science and practice of psychology" (p. 5); and that the chosen model "may be one identified through a national conference of psychologists, from which guidelines for professional education and training have been approved by the delegates" (p. 6).

The model began with the University of Illinois's short-lived Psy.D. program developed by Donald Peterson. In general, the practitioner-scholar model was a response to the view that the scientist-practitioner model overemphasized education for the production of university research and underemphasized preparation for the provision of psychological services.

The practitioner-scholar model in itself with the exception of one area has not received much criticism. McFall (2006, 2012), for example, sees the science training received by many Psy.D. students as inadequate for the production of the scientifically oriented professional psychologists that he sees as serving the field best. Most of the criticisms by him and others, including Donald Peterson, have been of the professional psychology movement, not the model (which is the focus of this article). They point to lower selection ratios (and therefore weaker students), larger classes, weaker faculties, and the location of programs in institutions outside of traditional universities.

The five central components that characterize the practitioner-scholar model will be addressed: (1) a broadened view of psychology, with a flexible epistemology, multiple ways of knowing, and a delineation of how practitioners *doing practice* remain *local clinical scientists* doing *disciplined inquiry*; (2) a description of the pedagogy of integrative experiences; (3) the professional core competencies and the requirements of a competency-based core curriculum in which practical and scientific knowledge, skills, and attitudes are integrated; (4) elements of practice, including multiple roles, the self of the professional psychologist and reflective practice, practicum and internship training, and systematic evaluation; and (5) the social nature of professional psychology and the public responsibility of the profession to serve the larger society, with special consideration of issues related to ethnic and racial diversity, and gender.

Psychological Science and Education for Professional Psychology

The most serious controversies and misunderstandings surrounding the practitioner-scholar model have concerned the role of science in the education of professional psychologists.

[†] Deceased.

All professional psychologists, whether PhD, or PsyD, are to be scientifically educated and trained in all aspects of their education, not just when they are conducting research or evaluation. Rigorous professional activity has traditionally been conceived as the application of scientific knowledge developed through laboratory experiments or controlled field research to the understanding and solution of human problems. In the practitioner-scholar model, practitioners engage the immediate challenge of providing services to people. Starting with the needs of each client, the practitioner-scholar model requires that practitioners bring the best available theoretical conceptions, the most useful available research, and their individual and collective professional experience to bear in studying and improving the functional condition of the client. Professional activity is not the application of knowledge derived from a separate scientific research process; it is a form of science and, indeed, a form of research in and of itself. The systematic process of scientific professional work has been characterized as 'disciplined inquiry' by Donald. R. Peterson (1991, 1995, 1996a,b). The role of the professional psychologist is that of the 'local clinical scientist' (Stricker and Trierweiler, 1995; Trierweiler and Stricker, 1992, 1998). These books and papers provide very detailed technical and epistemological arguments that go far beyond the brief summaries in this article. The properly trained professional psychologist is a scientist in the same sense that the skilled physician is a local clinical biological scientist and the skilled engineer a local physical scientist.

Nevertheless, the shift in viewpoint toward the local clinical scientist carries profound implications for the education of professional psychologists. Though most programs mandate dissertation research that contributes to general scientific knowledge as one central requirement of scientific education and training for all practitioners, the local clinical scientist model demands that situations and issues encountered by practicing professional psychologists to be examined in the course of graduate study as exercises in disciplined inquiry.

Within NCSPP, programs have taken an array of positions regarding the type of scholarly products integral to scientific education, ranging from requiring relatively small, clinically oriented doctoral projects to dissertations of the level and quality that might be found in traditional PhD programs. Those programs that require dissertations usually emphasize an applied focus that embodies a broader array of investigative approaches and a wider range of dissertation topics; all of which demonstrate an omnipresent emphasis on disciplined inquiry as basic to clinical education. Types of dissertations may include the following: (1) theoretical analyses; (2) surveys; (3) analyses of archival data; (4) outcome research, including program development and evaluation; (5) systematic qualitative investigations (6) public policy and legislative analysis; (7) case studies; and (8) group-based nomothetic investigations.

Throughout their careers, all practitioners are expected to retain a pervasive, deeply ingrained scientific outlook. A substantial number of graduates will take on the sorts of applied research listed above. Some will conduct professionally relevant, generalizable applied research, and a few will devote themselves to the traditional forms of research that preoccupy the faculties of most research universities. In a general way, these outcomes are not substantially different from those produced by traditional training models. The difference is that career expectations and educational experiences in the practitioner-scholar model are designed to match the realities of professional work in communities – as closely as they are now known and as clearly as they can be foreseen for the years ahead. These realities only rarely arise from traditional versions of the disciplinary core or from preparation for careers in academic research – careers that are unlikely to be available to the great majority of graduates, regardless of the program type.

The Practitioner as Local Clinical Scientist

NCSPP adopted Trierweiler and Stricker's (1992, 1998; Stricker and Trierweiler, 1995) vision of local clinical scientists who are "critical investigators of local (as opposed to universal) realities: (1) who are knowledgeable of research, scholarship, personal experience, and scientific methodology; and (2) who are able to develop plausible, communicable formulations for understanding essentially local phenomena using theory, general world knowledge including scientific research, and most important, their own abilities as skeptical scientific observers" (Trierweiler and Stricker, 1992: p. 104).

Scientific training in professional psychology is viewed as essential for developing and enhancing critical thinking in students, and it should be integrated throughout the curriculum. "Skills in local investigation and in problem solving (thinking on one's feet) assume unusual importance" (Trierweiler, 1992: p. 10). According to Trierweiler (1992), "the guiding metaphor becomes a Sherlock Holmes or a Jane Marple standing in direct confrontation with the constraints, mysteries, banalities, and surprises of unique realities, rather than the distant, conservative, skeptical, and abstractly speculative university-based scientist most of us have struggled with in our professional identities "(10–11).

Though the goals and forms of scientific training in professional programs differ from those in traditional programs, rigorous scientific training is equally important in both models of education.

Multiple Ways of Knowing

The broadened educational domain of professional psychology (e.g., its theories, research methods, and applications) is characterized by scholarly, disciplined thought that is grounded in science, the humanities, and personal and professional experiences, and is enhanced by interdisciplinary perspectives and a broad-based array of continually developing methods.

Reflexive professional psychology requires critical analysis of the theories that guide disciplined inquiry and the methods through which investigations are conducted. Reflective practice was first described by the Schoen Study in the early 1980s (see also D.R. Peterson, 1995; R.L. Peterson, 1992). These include the philosophical foundations of inquiry including, for example, epistemological and theoretical assumptions and implicit values (e.g., D.R. Peterson and R.L. Peterson, 1997) and the associated ethical issues, are therefore important in the education of professional psychologists.

The epistemological basis of disciplined inquiry in psychology must be comprehensive; responsive to wide-ranging, diverse, and fluid social contexts; and cognizant of invariably embedded values. This condition requires multiple ways of knowing that inform and enrich each other and that are appropriate and sensitive to the diverse populations to which they are applied. These ways of knowing include an enhanced array of methods drawn from related fields of inquiry – quantitative and qualitative, objective and subjective. In this context, research methods and theoretical formulations that increase understanding of women's issues and of diversity are stressed more strongly than they have been in the past.

In a typical case, to participate in disciplined inquiry, the necessary multiple ways of knowing require integrating material from the traditional scientific psychology knowledge base (including psychopathology, treatment approaches and outcomes, development, gender issues) with some relevant medical knowledge, the local economic circumstances and available resources, some history and relevant local historical narratives, knowledge about a local ethnic culture, a reasonably sophisticated understanding of a relevant religion, and, of course, the economic and service delivery issues, all working together in the context of a psychologist–client relationship. Though any particular requirements differ from situation to situation and client to client, the work of professional psychologists inevitably requires an array of multiple sources of data, collected in ways consistent with a variety of epistemologies.

Professional psychologists, in their roles as researchers, need explicit educational experiences to become self-critical with respect to the methodological, sociopolitical, and philosophical implications of inquiry. The integrative, reflective, educational experiences, described next as a central element of the NCSPP pedagogy, are just as relevant for the role of researcher as they are for the role of clinician. Conclusions should be carefully consistent with the limits of research designs, and particular consideration should be given to the likelihood of negative impact on underserved and diverse populations.

These positions, which may seem on the surface to be no more than bland ecumenical clichés, have general as well as clinical consequences. The areas of knowledge seen as relevant to professional psychology are greatly expanded. There is a strong movement away from narrow and doctrinaire conceptualizations of psychological science toward perspectives that oblige methodological multiplicity. Epistemology and critical thinking become more central to professional psychology training. An appropriate scientific basis for professional psychology demands an openness to the other groups and disciplines who share psychologists' concerns in a manner that emerges as an increased emphasis on ecological relevance (Peterson and Peterson, 1997). All of these ideas should be seen in contrast to the traditional scientific epistemology for psychology that appears in introductory texts and books on basic research.

Integrative Pedagogy

Even at this point in the portrayal of the NCSPP model, it is clear that the model necessitates a pedagogy of integrative experiences that is designed to educate students as local clinical scientists. To be more explicit, in this section we characterize the educational experiences and the contexts in which a conversation about a case becomes part of a student's learning. The integrative pedagogy of the NCSPP model can be seen as having the following seven aspects, including material described later as student development as a reflective process and explicit attention to relevant social issues such as marginalization, power, and authority.

Academic-scientific materials, both research and theory, including general information. Academic-scientific materials are used in combination with concepts and a process that facilitates local application (Stricker and Trierweiler, 1995; Trierweiler and Stricker, 1998). In a single learning experience, for example, materials might include critical discussions of information on a certain disorder, on possible treatments, on multiproblem clients and families, on ethical issues, on relevant issues of diversity, and on the economic realities of treatment, including the differences and contradictions that regularly appear in the literature.

Real examples and real experiences. These include the instructor's cases, cases seen under supervision, and live demonstrations and videos of students, instructors, and other practitioners. Students have the opportunity to engage in the real phenomena of professional psychology practice, so that disciplined inquiry can arise initially out of attention to the phenomena, not to a research problem.

The local, unique elements relevant to a particular client or professional situation (e.g., D.R. Peterson and R.L. Peterson, 1997; Trierweiler and Stricker, 1998).

Faculty and supervisory role models. Role models enthusiastically engage in the professional activities of the sorts that mirror the experiences students will encounter in clinical training and in their postgraduate practice.

Appropriate attitudes, including explicit ways of thinking like a psychologist. Thinking like a psychologist is integrated such that it will permeate all professional work.

Of course, depending on the program and the nature of the experience (whether, for example, a basic course with 30 students, a professional seminar of 8, or a supervision group of 4), different aspects of the pedagogy are emphasized. To take an example typical of many professional programs, an advanced student in a small group situation might present a diagnostic, conceptual, therapeutic, or ethical issue in a practicum case in light of the psychological literature for the feedback of the faculty leader and student colleagues. In such situations, the faculty person, and ultimately the students, should continually ask, "What have you observed?," "Why did you do that?," "What were the client's reactions?," "What is it like for you to sit with this client?," "How are these issues viewed by people of the same gender, ethnicity, and culture as the client?," "What, therefore, does this mean?," "What are your assumptions?," "How does this fit with your deeply held beliefs?," and, of course, "What is the evidence for your position?" or, "How do you know that?." As a presented case continues to unfold over time, different psychological literature may become relevant along with an evolving focus on the practice dilemmas that arise when a client's situation goes beyond the available readings. In doing so, participants become attuned to reflection and disciplined inquiry.

These integrative pedagogies have developed in an interesting variety of ways. All are designed to provide the best attainable professional service for each individual, group, or organizational case with which the students and faculty are concerned. Also, all are designed to be firmly embedded in the relevant scholarly knowledge, to reflexively educate the professional psychology graduate student, and to open doors that should lead to improved technologies and generalizable knowledge of relevance to the profession.

Core Curriculum and the Professional Core Competency Areas

The practitioner-scholar model has long been based on competencies. NCSPP articulated its initial work in the late 1980s and identified six competencies. A comprehensive statement was made in the original NCSPP model paper (Peterson et al., 1997). The descriptions below summarize much of the original material below plus diversity. Though not referenced, the language is drawn as closely as possible from the integrated resolutions and from papers describing these areas.

Relationship

Relationship is the capacity to develop and maintain a constructive working alliance with peers, colleagues, supervisors, members of other disciplines, consumers of services, and community organizations. The relationship competency is foundational to, and supportive of, all other competencies and is greatly impacted by students' awareness and connection to their self-identity. It involves the whole person and thus may include intellectual, emotional, cognitive, physical, cultural, and spiritual aspects, as well as the context or environment surrounding the person. Attitudes essential for the relationship competency, include, but are not limited to, (1) intellectual curiosity and flexibility, (2) open-mindedness, (3) belief in the capacity for change, (4) appreciation of individual and cultural difference (ICD), (5) personal integrity and honesty, and (6) belief in the value of self-awareness. These attitudes can be seen as embedded in the pedagogy of integrative experiences described earlier.

Assessment

Psychological assessment is a complex, integrative, and conceptual activity that involves deriving inferences from multiple sources of information to achieve a comprehensive understanding of a client or client system. It involves the ability to measure and formulate degree of need and mental status, develop psychological profiles in response to particular referral problems, and evaluate outcome with tests, measures, and diagnostic interviewing across a range of client populations. The assessment competency requires students to integrate data from multiple sources, to effectively answer referral questions, and to communicate their inferences and recommendations clearly.

Intervention

Intervention includes activities that promote, restore, sustain, and/or enhance positive functioning and a sense of well-being in clients through preventive, developmental, and/or remedial services. Development of competence in intervention requires understanding of theory and its application in personality, psychopathology, change processes, and the interactions and influences of social, environmental, cultural, and physiological factors.

Research and Evaluation

To give particular emphasis to the practitioner-scholar position on science and practice issues, the majority of the material on the research and evaluation competency has been presented earlier in the section titled *Psychological Science and Education for Professional Psychology*.

Consultation and Education

Consultation refers to the planned collaborative interaction between the professional psychologist and one or more clients or colleagues, in relation to an identified problem area or program. Psychological consultation is an explicit intervention process that is based on principles and procedures found within psychology and related disciplines, in which the professional psychologist has no *direct* control of the actual change process. Education is the directed facilitation by the professional psychologist of the growth of knowledge, skills, and attitudes in the learner. Competency in education involves knowledge about models of learning and pedagogy, as well as the foundations of, and innovations in, instructional design and evaluation. It also involves skill building in facilitating student knowledge acquisition and scholarly and personal development.

Management and Supervision

Management includes activities that organize, direct, or control services offered to the public. These activities require effective functioning within organizations, an understanding of financial management and strategic planning, and the ability to influence public and organizational policy. Supervision is a form of management and represents an intervention provided by a more senior member of a profession to a more junior member or members of the same profession. The relationship is evaluative, extends over time, and has the simultaneous purposes of enhancing the professional functioning of the more junior person, monitoring the quality of professional services offered to the client, and serving as a gatekeeper of those who are to enter the particular profession.

Because the majority of graduates of professional psychology programs are ultimately employed in positions requiring management and supervisory skills, NCSPP is convinced that this competency should occupy an enhanced status in the core curriculum. Going further, professional psychology programs

should support advanced preparation for leadership, advocacy, and public and social policy planning roles.

Diversity

The diversity competency requires the ability to identify and understand issues of Individual and Cultural differences (ICD), and issues of power, privilege, and oppression. This understanding informs and influences all professional functions and activities. Competency in diversity requires an affirmation of the richness of human differences, ideas, and beliefs. Important dimensions of diversity include (but are not limited to) age, disability and health, ethnicity, gender, language, national origin, race, religion and spirituality, sexual orientation, and social economic status, as well as the intersection of these multiple identities and multiple statuses. Exploration of power differentials, power dynamics, and privilege is at the core of understanding diversity issues and their impact on social structures and oppression.

In the last few years, NCSPP spelled out developmental achievement levels for each of the competencies. This work explains what is to be expected of students at each level as they move through their programs.

Knowledge Base

From the competency perspective, professional education is more inclusive but is, in fact, no less scientific. The professional competencies continue to be related to an evolving and developing knowledge base that should include the following areas: (1) biological bases of behavior, (2) cognitive-affective bases of behavior, (3) cultural bases of behavior, (4) dysfunctional behavior and psychopathology, (5) the historical and philosophical context of psychology, (6) life span development, (7) professional ethics and standards, (8) psychological measurement, (9) social bases of behavior, and (10) theories of individual and systems functioning and change. This has come to be known as the core curriculum and/or broad and general education.

Elements of Practice

In a context that reflects (1) the core competencies, (2) the wide range of activities in which professional psychologists are currently engaged and will be in the future, and (3) the likelihood of an expanded scope of practice in the future, the practitioner-scholar model has long emphasized the need to prepare psychologists for multiple roles. The educational process is not seen as one in which the student is pumped full of knowledge and skills that are then dispensed to the public for a price, but as an experience through which the personal and professional self of each student is systematically developed, consistent with ideas about reflective practice.

Multiple and Expanding Roles

The primary task of education in professional psychology is preparation for effective functioning in the multiple roles graduates will fill during the course of their careers. Conceptually, the idea of competencies is closely related to the idea of professional roles. Preparation for the wide array of roles evident in professional life is dependent on an education with a very broad understanding of each of the professional competencies.

The Self of the Professional Psychologist and Reflective Practice

Preparation in professional psychology involves the education of the personal and professional selves of students so as to develop the habits of reflective practice and lifelong learning. Awareness of self and self-other relatedness is central.

Both academic and interpersonal material relevant to inequalities of power and authority are key educational topics. All of these issues underscore the importance of training in both reflective practice and person-focused social and interpersonal sorts of professional development experiences that provide a context in which such conversations can occur. Different aspects of self and different ethical principles become relevant as professional psychologists move through multiple roles. Programs that educate professional psychologists carry an obligation to systematically attend to, develop, and evaluate the personal and interpersonal fitness of graduates.

Practicum and Internship Training

Recognizing that, for supervised practice in psychology, there is no one correct training model, the practitioner-scholar model strongly supports a diversity of practicum and internship models within professional psychology. The desirability of integrative service, inquiry, and teaching models in clinical training was reaffirmed. A strong relationship between educational coursework and field training is particularly valued.

Systematic Evaluation

NCSPP professional psychology educators have committed themselves to outcome and evaluation research to assess traditional and alternative models of training and service. There continues to be general affirmation of the need for systematic evaluation of students, programs (including faculty and supervisors), and services. Evaluation of professional competence in field experiences is based on a three-way learning contract among the student, the practicum or internship center staff, and the program faculty. Critical aspects of the evaluation process involve supervision; direct observation; and instruments and procedures incorporating self-evaluation, student peer evaluation, and program field faculty evaluation. Critical to an institution's ability to vouch for the quality of its graduates, competency-based clinical examinations are viewed as central to the training process. Such examinations should assess competence relevant to professional practice using

multimethod evaluation techniques (that might include live evaluation or other direct scrutiny of students' work by means of audiotapes and videotapes, written case presentations, examinations by faculty, and presentations to peers) as generally exemplified in the American Board of Professional Psychology (ABPP) examination. Professional psychology programs should not attend only to academic progress but are also responsible for evaluating students with regard to those personal attitudes, aptitudes, and values that appear likely to predict future professional competence. As the competency language (with knowledge, skills, and attitudes as the basic definition) has come to dominate psychology and medicine, these elements can be seen as part of *attitudes*.

Social Responsibility, Diversity, and Gender

The model has taken leadership in emphasizing the social nature of professional psychology and the social responsibilities of both programs and graduates. Against the backdrop of the history of education and training in psychology, NCSPP has believed that issues related to diversity and gender needed additional, particular attention as exemplified by developing its seventh competency of diversity.

Social Nature of Professional Psychology

Education must be socially responsive and responsible. A profession of psychology can be justified only if it meets the fundamental needs of the larger society. Professional practice in psychology and the education for that practice are fundamentally social, not private or individual. This social vision and understanding are apparent in a number of areas: (1) an examination of the importance of the socially situated role of psychologists, (2) the basic and underlying aspect of the relationship competency, (3) historical analyses of the social influences on the core curriculum in professional, (4) the development of the competency areas, (5) the necessity of directing explicit attention to the organizational contexts and cultures in which education occurs, (6) the interpersonal nature of reflective education, and (7) the development of a broad-based definition of social responsibility.

Implications for Professional Psychology

This work continues to have a number of implications for the training and practice of professional psychologists:

The competencies as a heuristic. The competencies and the competency model can be seen as a heuristic for the field. The overall model has and will continue to help psychology understand the growth of competencies from the beginning student to the graduate pursuing ABPP certification. The competency model organizes conversations about both current and expanded roles for the future, educational experiences leading to those roles, and credentialing for them.

Broad professional psychology education. Students are being educated in the broadest sense to be professional psychologists, not, to mention some stereotypes, psychotherapists with a few science courses or researchers with a few clinical courses.

Preparation for actual roles as practitioners. Graduates explicitly educated to become practitioners are likely to be better prepared to do what they actually do after graduation, as clearly as the realities can be known or the future foreseen. Often, practitioners trained in earlier times with narrower models had much to learn on their own about the professional world after receiving their doctorates.

Education for service delivery. Students who seek a career in psychology as a helping profession are educated in a model that is committed to service delivery as a primary value. Practitioners, specifically trained to serve in that capacity, may be more likely to retain connections with their programs and institutions in a way that will facilitate continuing education, enhance graduates' pride and acknowledgment of value in the work they are doing, and enhance mutual respect among differently trained psychologists.

Education relevant to social issues and diversity. Beyond the problems of individuals, the practitioner-scholar model provides the focus and background for dealing with social issues, with both sensitivity to and education about diversity.

More attention to consultation and education and to supervision and management. Expanded curricular attention still needs to be given to consultation and education and to supervision and management to reinforce that these activities are critical aspects of professional psychology practice.

Attitudes critical to professional development. This model values attention to attitudes as a critical aspect of professional development. These are the same attitudes, which along with knowledge and skills, comprise competencies. The competency movement now provides the dominant organizing vision in the education of professional psychologists as well as physicians. Further, the model articulates how the self of the student professional psychologist should be involved in reflective professional education and practice. Without substituting self for science, this reflexive model is consistent with, not divergent from, mainstream professional values. Education and practice involve the person of the professional psychologist, not only the narrow technical application of some scientific knowledge.

Science as implemented in psychological practice. Over the long term, on the basis of concepts like the local clinical scientist and disciplined inquiry, the most significant impact of this model may be to focus attention on how science is actually – and could be more effectively – applied in psychological practice. Though some of these conceptual pairs do denote bona fide and important differences, the practice of psychology as characterized in the concepts and examples of the local clinical scientist may bring these groups together because they identify common, desirable processes for practice that are based on disciplined inquiry and are in a language that is familiar across subcultures.

In many ways, there is a great degree of overlap between the practitioner-scholar model and the scientist-practitioner model. In best examples of each, there might be little disagreement, if there were agreement on which are the best examples. In less ideal cases, practitioner-scholar model advocates still might say that the Boulder model includes too much emphasis on the examination and production of career-irrelevant research, whereas the scientist-practitioner advocates might say that the science disappears in the focus

on clinical work. At bottom, though, there is a common interest; psychological science is an integrative, disciplined, reflexive way of thinking that helps all psychologists to work together to solve great and important human problems.

Abstract

Although some argue that the science and practice of psychology is as old as recorded history, contemporary psychology, as an evolving discipline, emerged at the end of the nineteenth century. From the beginning, the science and practice (or application) of psychology were inextricably woven together although few early psychologists embraced this model. This article reviews the history of clinical psychology training in the United States, with an emphasis on what is known as the "scientist–practitioner model."

Since the mid-twentieth century, scientist-practitioner training in clinical psychology has been the preeminent educational model for clinical psychologists. In 1949, 71 psychologists and educators held a 2-week meeting in Boulder, Colorado to define clinical psychology and propose a model of education and training. They recommended that clinical psychologists complete a doctor of philosophy degree in general psychology, marked by an empirical base and a grounding in the scientific method. They further recommended that such training be accompanied by practical experience including at least a year of a predoctoral internship. The report of the Boulder Conference set the stage for clinical psychologists to become both scientists and practitioners, a unique model among the major disciplines and professions. The scientist–practitioner model was embraced by and continues in most university-based, PhD-granting programs that educate and train clinical psychologists.

Although some argue that the science and practice of psychology is as old as recorded history, contemporary psychology, as an evolving discipline, emerged at the end of the nineteenth century. From the beginning, the science and practice (or application) of psychology were inextricably woven together although few early psychologists embraced this model. Experimental psychology was born in 1879 in Willhelm Wundt's laboratory in Leipzig, Germany and brought to the USA by numerous students who worked with him. They pursued rigorous scientific investigations of animal and human subjects specifically around learning, memory, and sensory processes. At about the same time in Vienna, Austria, Sigmund Freud was developing his 'talking cure' psychoanalysis, a clinical approach to the influence of trauma or past events on disruptive emotional symptoms often having to do with cognitive processes such as 'repression' or 'transference' (*see* Psychoanalysis, History of). But whatever the overlapping interest in learning, memory, and relearning, proponents of these two approaches had little to do with each other and a reapproachment between the scientific investigations of behavior and the clinical techniques of psychoanalysis was not offered until some 50 years later (Dollard and Miller, 1950).

The late nineteenth century was also a time of considerable debate about the etiology of mental illness. Physicians, such as Emil Kraepelin who had also studied with Wundt, embraced an organic model which proposed that manic-depressive psychosis and dementia-praecox (schizophrenia) would be found to have a biological basis similar to syphilis, for which the spirochetes causing the brain degeneration had just been found. Others assumed that psychological processes composed the underlying etiology of emotional and mental disorders. These debates were further couched within discussions about whether investigations of general behavior or a concern with individual differences would lead to new understandings about the nature of human behavior.

Lightner Witmer, the father of clinical psychology, was an extraordinary exemplar of a scientist–practitioner (**Table 1**). In his attempts to use psychology to help children who were having difficulty in school, Witmer was the first to write about the need to integrate the basic science of psychology and its

Table 1 A comparison of practitioner–researcher and scientist–practitioner models

	Practitioner	*Scientist*

Training goals	Practitioner–researcher	Scientist–practitioner
Career settings	Community mental health centers, colleges counseling centers, clinics, hospitals private practice	Colleges and universities, research agencies, medical schools
Admissions criteria	Human service interest and/or experience, interpersonal skills, intellectual abilities	Research interest and/or experience, interpersonal skills, intellectual abilities

application. In fact, he believed that there was no valid distinction between a pure science and an applied science.

Witmer founded the first Psychological Clinic at the University of Pennsylvania in 1896 and the first clinical journal, *The Psychological Clinic*, in 1907 (*see* Clinical Psychology in North America, History of). In the opening article of the journal, Witmer writes movingly of the difficulties he had finding ways to make psychology useful in his treatment of clients. One of his first cases was a 14-year-old boy referred by his teacher because he could not seem to learn to spell. Witmer (1996) looked to basic psychology but could not find "that the science of psychology had ever addressed itself to the ascertainment of the causes and treatment of a deficiency in spelling. Yet, here was a simple developmental defect of memory; and memory is a mental process of which the science of psychology is supposed to furnish the only authoritative knowledge. It appeared to me that if psychology was worth anything to me or to others it should be able to assist the efforts of a teacher in a retarded case of this kind" (p. 2). Witmer goes on to quote the President of the American Association for the Advancement of Science noting that "the final test of the value of what is called science is in its applicability…the pure and the applied sciences advance in a single front. What retards the progress of one, retards the progress of the other; what fosters one fosters the other" (Witmer, 1996: p. 2).

In an effort to bridge the science and practice of psychology, Witmer linked his psychological clinic to the psychology laboratory at the University of Pennsylvania. His clinical cases also comprised part of the curriculum for the child development courses. Witmer proposed a 'scheme of practical work in psychology' that laid the foundation of clinical, counseling, and school psychology. This consisted of the investigation of the phenomena of mental development by means of statistical and clinical methods, a clinic supplemented by a training school, practical experience for those working with children, and the training of students for a new profession – the psychological expert. Forty years later these guidelines were adopted almost in their entirety by the Boulder Conference on education and training in clinical psychology.

Numerous other children's psychological clinics were developed during the first few decades of the twentieth century. Usually these were associated with universities but some were established to provide clinical intervention for juvenile delinquents. Clinical psychologists were also working in facilities for the mentally retarded and became heavily involved in intelligence testing. Both basic and applied psychologists extended psychology's expertise in 'mental' testing to the assessment of recruits into the military during World War I. Unfortunately, this began one of the most tragic episodes in psychology's history – the use of intelligence testing to keep thousands upon thousands of immigrants from relocating in the USA.

Debates about appropriate educational and training models for the proper roles and functions of psychology began in the earliest days. Most psychologists, especially those who had trained with Wundt, envisioned psychology as an evolving science which would explore the intricate processes of consciousness and memory, unlock the mysteries of sensory processes, and answer questions about how people perceive and make sense of the world. Psychological findings would be based on the most rigorous of experimental methods. Other psychologists, faced with practical and poignant human problems, such as a child's failure to learn, believed that psychology could advance knowledge through a consideration of practical issues and problems and be immediately applied to help people in need.

While the parallels are not perfect, these differences in epistemological styles reflect a philosophical conflict of some 2500 years. A Socratic view of education places emphasis on curiosity and the accumulation of knowledge for its own sake while the Sophists emphasize human welfare and believe "man is the measure of all things" (Kimble, 1984). Within early psychology, William James (1907) described the history of philosophy as a constant battle between these two sharply contradictory intellectual styles. He described the 'tough-minded' skeptical, empirical scientific psychologists who depend only on facts versus the 'tender-minded' rational and idealistic sort who base their efforts on principles. James commented on the antagonisms between the 'unrefined, callous, or brutal' tough-minded and the 'sentimental, soft-headed,' tender-minded (James, 1907). Later, Snow (1964) wrote extensively about the clash of the 'two cultures' of science and humanism and Kimble (1984) extended this observation into psychology. Kimble suggests that contemporary psychology continues to have an identity problem in that the two cultures of the scientist and practitioner cannot agree on a coherent set of values.

This clash of cultures, as exemplified by the different values embraced by the scientific versus the practitioner psychologist has always been with us. As early as the turn of the twentieth century, applied and clinical psychologists were complaining that the newly formed American Psychological Association (APA) was not meeting their needs. Practicing psychologists were particularly concerned that they be recognized through some formal mechanism as having been trained in psychology. In 1917, an American Association of Clinical Psychology was proposed as a vehicle whereby psychologists who were qualified to perform psychological testing could be identified. With some reluctance, APA agreed to certify some members as 'consulting psychologists' and formed a Clinical Section. The primary mission of APA, however, was to promote psychology as a science.

As practitioners involved themselves in psychological testing, child guidance, and helping individuals with 'adjustment' problems, issues of ethics, licensing, and standardization of training became paramount. In the early 1930s, the New York Psychological Association in an effort to meet practitioner needs at a national level became the Association of Counseling Psychologists. They became so strong that in 1937 the Clinical Section of APA disbanded to join them in the new American Association for Applied Psychology (AAAP).

AAAP began to move across the national scene to meet the needs of practitioners and state affiliates in regard to uniform training, certification, public relations, and ethical conduct. The group proposed a model certification act to gain licensure or registration for qualified psychologists and published a membership directory to identify such practitioners for the public. They proposed an ethical code and pushed for a curriculum, both undergraduate and graduate, that would include applied and clinical psychology. Further, Carl Rodgers (1939) proposed a supervised, 1-year internship training for

clinical psychology graduate students and discussed the idea of a doctor of psychology degree, rather than the PhD (Napoli, 1981).

The advent of World War II had a powerful influence on organized psychology. In an effort to present a unified front for responding to the war efforts and the needs of the military, an Emergency Committee in Psychology was established that included representatives from all of the national psychology organizations (now up to six). A subcommittee on Survey and Planning for Psychology, chaired by Robert Yerkes, was formed to begin making long-range plans for psychology's future. Their first report deplored the splintering of psychology into various groups and proposed an increased emphasis on professional activities within the APA. They further proposed a new national organization that would serve both science and practice. When the war was over, the stage was set for the APA to reorganize to serve the needs of psychologists, whether their interests be basic or applied psychology. The two cultures of science and practice in psychology would be subsumed, once again, within one organization.

Psychologists had served in a number of capacities during World War II, ranging from the regular duties of the infantry to preparing propaganda and disseminating disinformation. Basic psychological scientists became involved in human factors designing user-friendly instruments for vehicles and planes. Clinical psychologists found themselves providing counseling and psychotherapy for soldiers and by the end of the war, some 450 clinical psychologists were serving in the US Army.

At the urging of the National Research Council, the disparate national groups of psychologists began to meet together at the end of the war. Acting on recommendations from the Yerkes committee, the APA revised its by-laws to "advance psychology as science, a profession, and a means of promoting human welfare" and incorporate other groups and representatives from state associations. The AAAP became the Clinical Division of APA and professional psychologists began to feel more at home in the then 4000 member organization.

The National Institute of Mental Health and the Veteran's Administration were eager for clinical psychologists to continue to provide services for veterans who were suffering psychological and emotional problems. In fact, they began to subsidize training to increase the numbers of psychiatrists and social workers. They were willing to do the same for clinical psychology if appropriate training programs could be identified. APA provided the names of 22 such university programs and appointed a Committee of Training in Clinical Psychology to determine how best clinical psychologists might be trained (American Psychological Association, 1947). The report of this Committee became the basis for a 1949 conference held in Boulder, Colorado which would recommend a revolutionary program of education and training. Clinical psychologists would be trained as both scientists and practitioners. Such an integrative model, unique among the major sciences and professions, would bridge scientific and humanistic traditions.

The Boulder conference was supported by the National Institute of Mental Health and the United States Public Health Service. Seventy-one representatives from universities, mental health service agencies, and allied professions met daily for 2 weeks to define clinical psychology and develop consensual standards for education and training. A 252-page book, *Training in Clinical Psychology*, reported the recommendations of the conference which were both comprehensive and specific (Raimy, 1950). Clinical students' attributes were enumerated, faculty described, and curriculum proposed. Clinical psychologists were to be trained in general psychology and demonstrate research competence culminating in a doctoral (PhD) dissertation. Further, students would engage in field training and a predoctoral internship so that they would be skilled in clinical assessment, diagnosis, and treatment. Such education and training was to take place in universities and internship facilities accredited under the auspices of the APA.

During the second half of the twentieth century, the Boulder or scientist–practitioner model became the preeminent mode of education and training in clinical psychology. Admissions to university-based, PhD-granting programs were, and continue to be, highly selective. Academic requirements include general areas of psychology such as history and systems and psychopathology as well as cognitive, developmental, experimental, personality, physiological, and social psychology. Students are expected to learn to conduct research and be familiar with the various statistical methods necessary to evaluate results. Further requirements include practical training in assessment and intervention under close supervision including a 1-year predoctoral internship. The scientist–practitioner model has been reaffirmed at each major graduate educational conference held since Boulder although a professional model was also recommended at a 1973 conference held in Vail, Colorado (Strickland, 1985, 1987, 1998).

The scientist–practitioner model is not reserved solely for clinical psychology. Other applied areas in psychology such as counseling and industrial–organizational psychology also embrace this paradigm as do the specialty areas of aging and health. For those who believe that psychology is a continually evolving discipline and field, basic training in science would seem essential in producing new knowledge. Further, practical training within such a model should lead to state-of-the-art applications. An integration of science and practice allows the continued interplay between scientific knowledge and clinical application where each informs the other.

Many would maintain that the development of the scientist–practitioner model has been one of psychology's finest achievements. Certainly for a newly evolving science which has clear implications for application, this novel educational and training approach gives the field vitality and direction. Embracing the two cultures of science and humanism, the scientist–practitioner model has not been an easy one for individual psychologists to achieve. But, scientist–practitioners have served psychology and society well both through advancing knowledge and applying that knowledge for the greater good.

Transaction Costs and Property Rights

Abstract

Property rights concepts and thinking go back to antiquity, but it was only in the 1960s, when the concept of transaction costs was introduced into the analysis of property rights by Ronald Coase, that the modern treatment of property rights got underway. Applications to externalities, common pool problems, variable access, the theory of the firm, rent seeking, economic development and reform, and *de facto* property rights are sketched. Although property rights concepts and property rights thinking have gone a long way to reshape our understanding of economic institutions and effect public policy reform, the early ambitions of the economics of property rights have been realized incompletely. Here, as elsewhere, there can be too much of a good thing. Examples include unduly sanguine recommendations to jetison regulation, over-reaching interpretations of the modern corporation, and undue reliance on mass and rapid privatization as the way to implement economic reform.

Transaction costs and property rights are related, important, and expansive concepts. Both move beyond technology to introduce law and organization. Both deal with issues of first-order economic importance (as against nuances). Because both have been difficult to operationalize, both have been used expansively and tautologically.

Property rights is the older concept, going back to antiquity. The use of transaction cost reasoning in the 1960s brought new life to the property rights movement. Not only is the economics of property rights basic, enduring, and important in its own right, but it also helped to usher in and remains an important part of the new institutional economics: 'Modern institutional economics focuses on the institution of property and on the systems of norms governing the acquisition or transfer of property rights' (Furubotn and Richter, 1991, p. 7). Of the various categories of property rights, the right of ownership – which consists of the right to use an asset, the right to appropriate the returns from an asset, and the right to change its form, substance, or location (Furubotn and Richter, 1991, p. 6) – is the most important.

The article begins with a sketch of the antecedents, then some of the leading property rights successes are examined, followed by the limitations and the conclusion.

Antecedents

Frank Michelman (1967) traces property rights concepts and thinking from Aristotle through the Christian Fathers, John Locke, David Hume, Jeremy Bentham, and Oliver Wendell Holmes. Despite this early and continuing interest, the economics of property rights 'has not been discussed analytically until very recently' (Demsetz, 1998, p. 144). The introduction of transaction cost reasoning into the study of property rights in the 1960s is responsible for much of the analytical advance.

Modern Property Rights

Externalities

Work on the economics for property rights flourished in the 1960s. Leading contributors included Ronald Coase (1959, 1960), Armen Alchian (1961, 1965), and Harold Demsetz (1967). Much of this work contested the orthodox interpretation of externalities as 'market failures' for which government intervention 'in the form of taxes, or subsidies, or regulation' was presumptively warranted. Rather than take property rights assignments as given, Coase moved the analysis back a step to examine the ramifications of reassigning property rights. His treatment brought out 'the reciprocal nature of the relationship which tends to be ignored by economists who, following Pigou, approach the problem in terms of a difference between private and social producers but fail to make clear that the suppression of the harm which A inflicts on B inevitably inflicts harm on A. The problem is to avoid the more serious harm' (Coase, 1959, p. 24). Assessing the more serious harm entailed introducing transaction costs.

Coase proceeded in a two-part way. Starting with the assumption of zero transaction costs, Coase advanced the (then) revolutionary proposition that 'the delimitation of rights is an essential prelude to market transactions; but the ultimate result (which maximizes the value of production) is independent of the legal [award of property rights to one party rather than the other]' (Coase, 1959, p. 25). This is because, distributional considerations aside, the parties will bargain to the same efficient result whichever way property rights are awarded.

For Coase, however, this was an expositional device. The real world is one of positive transaction costs, whereupon the assignment of property rights one way or another does matter. Efficiency now turns on the differential transaction costs of assigning property rights one way rather than another. Coase furthermore contested the idea that a 'benign government' could be used to correct market failures, it being the case that all feasible forms of organization are flawed (Coase, 1964). He also advised that total as well as marginal conditions needed to be included in a comparative assessment: there is a need to 'compare the total product yielded by alternative social arrangements' (Coase, 1960, p. 42). This comparative approach in which transaction costs are featured reshaped the study of property rights, market failures, and economic organization in the ensuing years, up to and including the present.

Common Pool Problems

Common pool problems arise in a variety of contexts, of which common grazing land (Hardin, 1968), fisheries (Turvey, 1964), petroleum extraction (Libecap and Wiggins, 1985), and water and air pollution are familiar examples. Whereas the externalities examined by Coase were predominantly of a bilateral kind, the common pool problem poses the need to coordinate many actors. Additional problems arise because (1) different actors are differently situated, (2) the relevant information is dispersed and costly to verify, (3) strategizing and politicking often arise, and consent is needed to, (4) agree on an overarching plan, and (5) craft an organization to implement whatever plan is agreed to. The need for political action and regulation often arises in efforts to reach and enforce collective agreements in the multiactor context.

Recourse to public ordering, is not, however, the only or always the best response. Private ordering can and has successfully mitigated many common pool problems (Furubotn and Richter, 1997, p. 102). Government assistance – for unitizing common pools (such as oil) or for creating markets (as in the creation of tradeable property rights for air pollution) – is often the cost-effective way to proceed.

Variable Access

The simplest transaction is an outright sale. But even that is complicated by the question of how the property right is defined. As Demsetz observes, 'To have the right to till a parcel of land is not equivalent to having all the rights to the land. Others may have rights both to minerals contained in the land and to trespass across the parcel. The identification of the owner of the asset is made more difficult by the virtually infinite number of different rights that can be associated with use of a given asset' (1998, p.145).

Access arrangements other than sale include leasing, tenant farming, inside contracting, and franchising. These can vary in length and protections. Incentives for due care (where the concern is over negligence by the lessee) and assured compensation for unexpired improvements (where the lessor stands to gain by refusing compensation for improvements made by the lessee that extend beyond the length of the lease) are common concerns. Access terms is also an area where the risk of changes in the political rules of the game is a chronic concern, the imposition of rent control being one example and the arbitrary exercise of imminent domain and 'takings' by the state being another (Michelman, 1967).

Theory of the Firm

The theory of the firm poses numerous property rights issues, of which the most famous is the separation of ownership from control to which Adolf Berle and Gardiner Means (1932) made early reference in the context of the large corporation where shareholding is widely dispersed. Thus although shareholders remain *de jure* owners in the large corporation, effective or *de facto* ownership purportedly passes to the management. Berle and Means thereupon questioned the presumption that firms are reliably given to profit maximization.

Analytical reactions to this condition of separation have varied. One response has been to dismiss the issue by assuming that competition in product and capital markets is relentlessly taut. As Tjalling Koopmans has observed, however, 'if this is the basis of our belief in profit maximization, then we should postulate that basis itself and not the profit maximization which it implies in certain circumstances …. It would lead us to expect profit maximization to be most clearly exhibited in industries where entry is easiest and where the struggle for survival is keenest, and would present us with the further challenge to analyze what circumstances give to an industry that character' (1957, pp. 140–1).

Another response to the separation of ownership from control is to reformulate the objective function to reflect *de facto* control rights. The sales maximization hypothesis (Baume, 1959), growth maximization hypothesis (Marris, 1964), and managerial discretion hypothesis (Williamson, 1964) are in this spirit. Still another response is to reconceptualize the problem of organization in contracting terms. The 'nexus of contract' approach (Jensen and Meckling, 1976) brings out agency cost features to which monitoring is a response, while the governance structure approach (Williamson, 1975, 1985) treats organization form as a decision variable. According to the latter, hierarchical decomposition principles – especially between centralized and decentralized modes of organization – matter. Organization is thus viewed both as a source of the managerial discretion problem and a partial solution, in that the large corporation can be reconfigured to mitigate some of its own failures.

A 'modern' property rights theory of the firm, of which Oliver Hart (1995) is the principal architect, has taken shape more recently. This theory works out of an incomplete contracting setup. The central issue with which this theory is concerned is that of vertical integration: who should own the assets of two related stages of production? This theory illustrates both the strengths and limitations of property rights reasoning. To its credit, the analysis makes clear how the ownership of property rights influences *ex ante* investments. But this exclusive focus on property rights comes at a cost, in that problems of *ex post* maladaptation are suppressed (by assuming that the parties will costly bargain to an efficient result, whatever the assignment of property rights). The idea that organization matters – that the management of some transactions is better done by markets and of others by hierarchy – is sacrificed in the process.

Rent Seeking

The *de facto* ownership of property rights poses numerous intertemporal issues, of which rent seeking is one. The basic rent seeking proposition is this: the creation of 'rights' to which supernormal returns potentially accrue invites *ex ante* prepositioning, thereby to better qualify the applicant/bidder for the job or contract in question. For example, the award of a natural monopoly franchise or of a favored class of employment (Civil Service) invites parties to politick to receive the award and to make other efforts to improve their eligibility. Rent protective efforts also ensue (Tollison, 1998).

In the degree to which such responses went unnoticed or were ignored by economists, such costs were mistakenly omitted from the original calculus. Upon 'discovering' such costs, most economists declared them to be wasteful. That, however, assumes that economics trumps politics (Stigler, 1992). If political choices are to be respected, then the best course of action is to recognize that prepositioning is a predictable consequence of efforts to create new classes of rights, whereupon prepositioning effects are folded into the project design calculus. In that event, rent seeking, and its attenuation, are included in the 'approved plan.' Those who condemn rent seeking are loathe to come to terms with this proposition.

Economic Development and Reform

Early development theory emphasized 'macroeconomic accounting aggregates such as savings and the balance of payments, and the relative balance between broadly defined "sectors" such as "industry" and "agriculture"' (Lal, 1983, p. 5). When that prescription proved disappointing, the pendulum swung in the opposite direction. The new imperative was to activate the market and 'get the prices right' (Lal, 1983, p. 107), but that too was overly simple.

'Getting the property rights right' seemed more responsive to the pressing needs for reform in Eastern Europe and the former Soviet Union. But while 'an essential part of development policy is the creation of polities that will create and enforce efficient property rights, … we know very little about how to create such polities' (North, 1994, p. 366). As discussed in Section Russian privatization, privatization is important but is not a panacea.

De Facto Property Rights

Just as the study of contract has benefited by going beyond a legal rules concept of contract to make prominent provision for private ordering (Llewellyn, 1931; Galanter, 1981), so too does the study of property rights benefit by going beyond *de jure* property rights to consider *de facto*. The recent application of *de facto* reasoning to explain economic development and reform in China (Qian and Weingast, 1996) is illustrative. The dilemma was this: *de jure* privatization was politically unacceptable, yet the state-owned enterprises in China had weak incentives and poor performance. What to do?

Decentralization, by creating local township and village enterprises in which local government remained prominent, turned out to be a productive move. As Qian and Weingast put it (1996, pp. 87–8):

> These local government-owned enterprises have remarkably different governance structures from (central) state-owned enterprises and thus face better positive and negative incentives…. Politicians in every political system tend to bail out inefficient firms or spend on wasteful consumption. In a federal system, however, the mobility of resources across regions raises the opportunity costs to local governments of bailing out inefficient firms or wasteful public expenditures.

Not only do local governments share the successes of local enterprises, but they incur the risk that investments will relocate if governments interfere. Federalism is thus an instrument for realizing quasi-privatization and the incentive benefits that accrue thereto. *De facto* property rights thus vary with the political environment, *de jure* property rights unchanged.

There are nevertheless limits to the risks that parties will incur in a regime where *de jure* credibility is lacking. I conjecture that China will experience serious incentive obstacles in its attempts to develop leading edge technologies unless it provides more secure *de jure* supports for intellectual property rights.

Limitations

Although property rights concepts and property rights reasoning have gone a long way to reshape our understanding of economic institutions and effect public policy reform, the early ambitions of the economics of property rights have been incompletely realized. Here, as elsewhere, there can be too much of a good thing.

Oversimplification

According to Coase, 'a private-enterprise system cannot function properly unless property rights are created in resources, and, when this is done, someone wishing to use a resource has to pay the owner to obtain it. Chaos disappears; and so does the government, except that a legal system to define property rights and to arbitrate disputes is, of course, necessary' (Coase, 1959, p. 12).
